Third Edition (September 2008)

This edition applies to Version 1 Release 9 of z/OS (5694-A01) and to all subsequent releases and modifications until otherwise indicated in new editions.
3.22 Restarting JES2 ................................................. 164
3.23 Stopping JES2 .................................................. 166
3.24 JES2 operations ................................................ 168
3.25 Controlling the JES2 environment. .......................... 170
3.26 Controlling a MAS environment ............................. 171
3.27 Controlling JES2 spooling ................................. 172
3.28 Controlling JES2 jobs ....................................... 173
3.29 Controlling JES2 printers ................................... 174
3.30 JES3 processing ............................................... 176
3.31 JES3 configuration ........................................... 177
3.32 JES3 complex ............................................... 179
3.33 MVS and JES3 environment ................................. 180
3.34 JES3 global ..................................................... 182
3.35 JES3 sysplex components ................................... 184
3.36 JES3 multisystem sysplex ................................. 185
3.37 JES3 global functions ....................................... 187
3.38 JES3 terminology ............................................ 188
3.39 JES3 single LPAR ............................................ 190
3.40 JES3 multiprocessing ........................................ 191
3.41 JES3 spooling ................................................. 193
3.42 JES3 job flow .................................................. 195
3.43 JES3 job flow (2) .............................................. 196
3.44 JES3 job flow review ......................................... 198
3.45 JES3 job flow: Scheduler elements ......................... 200
3.46 JES3 standard job ............................................ 202
3.47 JES3 non-standard job ....................................... 203
3.48 Creating a batch job ......................................... 204
3.49 Converter/interpreter processing ........................... 205
3.50 Main scheduler element ....................................... 206
3.51 Main device scheduling (MDS) ............................. 207
3.52 Main scheduler element processing ......................... 208
3.53 OUTSERV scheduler element processing .................. 209
3.54 Output service processing ................................... 210
3.55 Purge processing .............................................. 211
3.56 JES3 functions not in JES2 .................................. 212
3.57 Dynamic support program (DSP) ........................... 214

3.68 Start JES3 with a hot start .................................. 227
3.69 JES3 DLOG function ......................................... 229
3.70 JES3 start procedure .......................................... 230
3.71 JES3 initialization stream ................................... 232
3.72 JES3 startup messages ....................................... 234
3.73 JES3 startup .................................................... 235
3.74 JES3 messages following *S JSS ......................... 236
Chapter 4. LPA, LNKLST, and authorized libraries ............................................. 249
4.1 The creation of an executable program .................................................. 250
4.2 Link pack area (LPA) .............................................................................. 252
4.3 LPA subareas ......................................................................................... 254
4.4 Pageable link pack area (PLPA) ............................................................. 256
4.5 LPA parmlib definitions ......................................................................... 257
4.6 Coding a LPALSTxx parmlib member ..................................................... 259
4.7 Fixed link pack area .............................................................................. 260
4.8 Coding the IEAFIXxx member ............................................................... 261
4.9 Specifying the IEAFIXxx member .......................................................... 262
4.10 Modified link pack area (MLPA) ........................................................... 263
4.11 Coding the IEALPAxx member ............................................................. 264
4.12 Specifying the IEALPAxx member ........................................................ 266
4.13 Dynamic LPA functions .................................................................... 267
4.14 The LNKLST ...................................................................................... 268
4.15 Dynamic LNKLST functions ................................................................. 270
4.16 Library lookaside (LLA) ..................................................................... 271
4.17 CSVLLAxx SYS1.PARMLIB member .................................................... 273
4.18 Compressing LLA-managed libraries .................................................. 276
4.19 Virtual lookaside facility (VLF) ............................................................. 278
4.20 COFVLFx xx parmlib member ............................................................... 280
4.21 Authorized program facility (APF) ....................................................... 283
4.22 Authorizing libraries ........................................................................... 285
4.23 Dynamic APF functions ...................................................................... 287

Chapter 5. System Modification Program/Enhanced (SMP/E) .............................. 291
5.1 SMP/E overview .................................................................................. 292
5.2 SYSMODs ............................................................................................ 294
5.3 Concept of SMP/E elements ................................................................ 296
5.4 Changing the elements of the system .................................................... 298
5.5 Fixing problems with an element (PTF SYSMOD) ................................. 299
5.6 Fixing a problem with an element (APAR SYSMOD) ......................... 300
5.7 Customizing an element (USERMOD SYSMOD) ................................. 301
5.8 PTF replacement ................................................................................ 303
5.9 PTF prerequisite ................................................................................ 304
5.10 Load module construction .................................................................. 305
5.11 Data sets used by SMP/E .................................................................. 306
5.12 Dynamic allocation of SMP/E data sets .............................................. 309
5.13 How dynamic allocation works ............................................................ 311
5.14 Consolidated software inventory (CSI) ............................................... 313
5.15 How to organize CSI data sets ............................................................ 315
5.16 Defining zones for your system ............................................................ 317
5.17 SMP/E commands you need to know ............................................... 319
5.18 The RECEIVE process ....................................................................... 321
5.19 Sources of HOLDDATA ..................................................................... 323
5.20 Reports for RECEIVE processing ....................................................... 324
5.21 RECEIVE examples ........................................................................... 327
5.22 The REJECT process .......................................................................... 330
5.23 REJECT examples .................................................. 332
5.24 The APPLY process .................................................. 335
5.25 APPLY examples .................................................. 338
5.26 The APPLY CHECK process ........................................ 340
5.27 The RESTORE process ............................................ 342
5.28 Restore examples .................................................. 344
5.29 The ACCEPT process ................................................ 346
5.30 ACCEPT examples .................................................. 349
5.31 Other useful SMP/E commands .................................... 351
5.32 Using the LIST command ........................................... 353
5.33 Using the REPORT ERRSYSMOD command ...................... 355
5.34 SMP/E dialogs ...................................................... 359
5.35 Customize the SMP/E dialogs ...................................... 360
5.36 Query selection menu .............................................. 362
5.37 CSI query panel ..................................................... 363
5.38 CSI query - Select entry ............................................ 364
5.39 CSI query - SYSMOD entry ......................................... 365
5.40 Building SMP/E jobs using the dialog ............................. 366
5.41 Command generation - Selection menu .............................. 367
5.42 Command generation - Select zone ................................ 368
5.43 Command generation - LIST command ............................... 369
5.44 Command generation - LIST global zone SYSMOD options .... 370
5.45 Command generation - List FORFMID ............................... 371
5.46 Command generation - Selection menu .............................. 372
5.47 Command generation - SUBMIT .................................. 373
5.48 The generated job .................................................. 374
5.49 Java archive (JAR) file support ..................................... 375
5.50 GIMZIP and GIMUNZIP service routines ......................... 376
5.51 GIMXSID service routine .......................................... 383

Chapter 6. Language Environment ....................................... 385
6.1 Language Environment (LE) ........................................ 386
6.2 Assembler language and programs .................................. 387

Preface

The ABCs of z/OS® System Programming is an eleven volume collection that provides an introduction to the z/OS operating system and the hardware architecture. Whether you are a beginner or an experienced system programmer, the ABCs collection provides the information that you need to start your research into z/OS and related subjects. If you would like to become more familiar with z/OS in your current environment, or if you are evaluating platforms to consolidate your e-business applications, the ABCs collection will serve as a powerful technical tool.

This volume describes the basic system programming activities related to implementing and maintaining the z/OS installation, and provides details about the modules used to manage jobs and data. The topics covered are:

- Overview of the parmlib definitions and the IPL process. The parameters and system data sets necessary to IPL and run a z/OS operating system are described, along with the main daily tasks for maximizing performance of the z/OS system.
- Basic concepts related to subsystems, how to use the subsystem services provided by IBM® subsystems, and planning considerations for setting up and writing your own subsystem.
- Job management in the z/OS system using the job entry subsystems JES2 and JES3. Detailed discussion of how JES2 and JES3 are used to receive jobs into the operating system, schedule them for processing by z/OS, and control their output processing.
- The link pack area (LPA), LNKLST, authorized libraries, and the role of VLF and LLA components.
- SMP/E
- Language Environment®

The contents of the volumes are:

Volume 1: Introduction to z/OS and storage concepts, TSO/E, ISPF, JCL, SDSF, and z/OS delivery and installation

Volume 2: z/OS implementation and daily maintenance, defining subsystems, JES2 and JES3, LPA, LNKLST, authorized libraries, SMP/E, and Language Environment

Volume 3: Introduction to DFSMS™, data set basics, storage management hardware and software, VSAM, System-managed storage, catalogs, and DFSMStvs

Volume 4: Communication Server, TCP/IP and VTAM®

Volume 5: Base and Parallel Sysplex®, System Logger, Resource Recovery Services (RRS), global resource serialization (GRS), z/OS system operations, automatic restart management (ARM), Geographically Dispersed Parallel Sysplex™ (GDPS®), availability in the zSeries® environment

Volume 6: Introduction to security, RACF®, Digital certificates and PKI, Kerberos, cryptography and z990 integrated cryptography, zSeries firewall technologies, LDAP, Enterprise identity mapping (EIM), and firewall technologies

Volume 7: Printing in a z/OS environment, Infoprint Server and Infoprint Central
Volume 8: An introduction to z/OS problem diagnosis

Volume 9: z/OS UNIX® System Services

Volume 10: Introduction to z/Architecture®, zSeries processor design, zSeries connectivity, LPAR concepts, HCD, and HMC

Volume 11: Capacity planning, performance management, WLM, RMF™, and SMF

The team that wrote this book

This IBM Redbooks® publication was produced by a team of specialists from around the world working at the International Technical Support Organization, Poughkeepsie Center.

**Paul Rogers** is a Consulting IT Specialist at the International Technical Support Organization, Poughkeepsie Center. He writes extensively and teaches IBM classes worldwide on various aspects of z/OS, z/OS UNIX, and Infoprint Server. Before joining the ITSO 20 years ago, Paul worked in the IBM Installation Support Center (ISC) in Greenford, England providing OS/390® and JES support for IBM EMEA and the Washington Systems Center. He has worked for IBM for 41 years.

**Alvaro Salla** worked for IBM for more than 30 years, specializing in large systems. He has co-authored many IBM Redbooks publications and spent many years teaching about large systems from S/360™ to S/390®. Recently retired from IBM, Alvaro continues to share his vast knowledge about these topics as a consultant for various ITSO documentation projects. He has a degree in Chemical Engineering from the University of Sao Paulo, Brazil.

Thanks to the authors of the previous editions of this book.

* Authors of the first edition, ABCs of z/OS System Programming Volume 2, published in August 2003, were:
  
  **Miriam Gelinski** is a staff member of Maffei Consulting Group, where she is responsible for supporting customer planning and installing zSeries software. Miriam holds a bachelor degree in Information Systems from Universidade São Marcos. Before joining Maffei Consulting Group, she worked for IBM zSeries brand for two years, where she was responsible for implementing new workloads on zSeries.

  **Sergio Munchen** is a system analyst at Banco do Brasil. He has four years of experience in the mainframe environment. His areas of expertise include assembler programming, customization of coupling facility exploiters, z/OS and HCD. Sergio holds a specialist degree in Computer Science from Universidade Federal de Santa Catarina.

  **Joao Natalino Oliveira** is a certified IT consulting specialist for IBM zSeries in Brazil, where he provides support for Brazil and Latin America. He has 28 years of experience in large systems, including MVS™, OS/390, and z/OS. His areas of expertise include performance and capacity planning, server consolidation, and system programming. He holds a bachelor degree in Mathematics and Data Processing from Fund. Santo Andre, Brazil.

* Authors of the second edition, ABCs of z/OS System Programming Volume 2, published in February 2006, were:

  **Joao Natalino Oliveira** (biography included with first edition authors)

  **Monica Mataruco** is a system programmer at ABN AMRO Real Bank in Brazil. She has 18 years of experience in large systems, including MVS, OS/390, and z/OS. Her areas of
expertise include installation and customization of the operating system and other z/OS components.

Julio Grecco Neto is a system programmer at ABN AMRO Real Bank in Brazil. He has 28 years of experience in large systems, including MVS, OS/390, and z/OS and DASD. His areas of expertise include installation and configuration of hardware and storage.

Antonio Orsi is a system programming manager at ABN AMRO Real Bank in Brazil. He has 31 years of experience in large systems, including MVS, OS/390, and z/OS. His areas of expertise include hardware and software configuration.

Become a published author

Join us for a two- to six-week residency program! Help write an IBM Redbooks publication dealing with specific products or solutions, while getting hands-on experience with leading-edge technologies. You'll team with IBM technical professionals, Business Partners and/or customers.

Your efforts will help increase product acceptance and customer satisfaction. As a bonus, you'll develop a network of contacts in IBM development labs, and increase your productivity and marketability.

Find out more about the residency program, browse the residency index, and apply online at:

ibm.com/redbooks/residencies.html

Comments welcome

Your comments are important to us!

We want our Redbooks to be as helpful as possible. Send us your comments about this or other Redbooks in one of the following ways:

- Use the online Contact us review redbook form found at:

z/OS implementation and daily maintenance

Regardless of which method you use to install the z/OS operating system (ServerPac or CBPDO), it is highly recommended that you understand the basic aspects of the z/OS implementation, from installation to preparing for daily activities after IPL. Installing means to create data sets in your DASD volumes that will receive z/OS data and z/OS programs sent by IBM through tapes or network media.

This chapter gives you an overview of the basics as well as the IPL process. It describes the main parameters and system data sets necessary to IPL and run a z/OS operating system, and the main daily tasks that a system programmer performs to maximize the advantages that a well-implemented operating system can offer to your IT structure.
1.1 Basic aspects of z/OS implementation

When you build a z/OS system, you must balance the needs of your installation to build one that meets its needs well. While this will sometimes mean compromise, it more often means finding ways to build a flexible system that is easy to install, easy to migrate, easy to extend, and most important, easy to manage. When applied well, using a well-planned structure, this flexibility can be used to control the time it takes to install and migrate new systems or new software levels throughout an installation.

A phased approach will often prove most feasible and can begin to control the installation and migration workload in the least time. This provides you benefits, starting with the next installation and migration cycle, while controlling the work involved in implementation.

Some aspects you might have to consider in adopting a structured approach to installation are:

- SYS1.PARMLIB and parmlib concatenation (logical parmlib)
- Catalogs and indirect catalog entries
- Separating data from software
- Placing data sets on specific volumes
- Choosing a naming convention for data sets
- DASD space utilization and performance
- System and installation requirements
1.2 SYS1.PARMLIB

Overview of parmlib members
SYS1.PARMLIB is a required partitioned data set (PDS) that contains IBM-supplied and installation-created members, with lists of system parameter values. You can include user-written system parameter members in parmlib before installing a product. Because SYS1.PARMLIB can be concatenated with other PDSs, we use in this book the name parmlib to refer to all the concatenated libraries and SYS1.PARMLIB when specific to a member.

Parmlib is read by the system at IPL, and later by many components and subsystems that use parmlib members to implement dynamic changes in the system through operator commands, such as:

- Workload Manager (WLM) with IEAOPTxx member
- Virtual Lookaside Facility (VLF) with COFVLFxx member
- Generalized Trace Facility (GTF)
- System Management Facility (SMF) with SMFPRMxx
- TIOC Terminal I/O Coordinator (TIOC) from TSO with the IKJPRM00 member, and many others

The purpose of parmlib is to provide many customization parameters in a pre-specified form in a single concatenated data set, and thus minimize the need for the operator to enter
parameters. The parmlib data sets can be blocked and can have multiple extents, but must reside on a single volume, like any PDS data set.

Note: This is one of the most important data sets in a z/OS operating system.

There are several concatenated parmlibs through definitions in the LOADxx member. Refer to “Logical parmlib and master JCL” on page 9 for further discussion.

**Defining SYS1.PARMLIB members**

All parameters of the SYS1.PARMLIB data set are described in the *z/OS MVS Initialization and Tuning Reference*, SA22-7592. Three of the most important members are discussed in this chapter. They are as follows:

- **IEASYSxx**  This member allows the specification of system parameters that are valid responses to the IEA101A SPECIFY SYSTEM PARAMETERS message that is displayed during the IPL process, as shown in Figure 1-17 on page 30. Multiple system parameter lists are valid. The list suffix is chosen by the operator SYSP parameter or through the SYSPARM statement of the LOADxx parmlib member. All the parameters in this member are used to customize z/OS and its subsystems.

- **IEASYMxx**  This member specifies, for one or more z/OS in a multisystem environment, the static system symbols that will suffix IEASYSxx parameters that a specific z/OS system is to use. These symbols allows a system to share, for example, the same SYS1.PARMLIB between z/OS systems by transforming generic parameters into specific ones for a single z/OS instance. One or more IEASYMxx members are selected using the IEASYM parameter in the LOADxx parmlib member. Refer to “System symbols” on page 5.

- **LOADxx**  This member contains information about the name of the IODF data set (which describes each z/OS I/O configuration), which Master catalog to use, and which IEASYSxx members of SYS1.PARMLIB to use.
1.3 System symbols

- **Dynamic system symbols**
  - Substitution text changes often

- **Static system symbols**
  - Substitution text is fixed at system initialization
  - Two types of static symbols
    - System-defined
    - 
    - Static system symbols
      - 
    - Installation-defined

---

**Defining system symbols**

System symbols are elements that allow systems to share parmlib definitions while retaining unique values in those definitions. System symbols can also be used in JCL and in IPCS (the component that formats memory dumps) procedures. System symbols act like variables in a program; they can take on different values, based on the input to the program. When you specify a system symbol in a shared parmlib definition, the system symbol acts as a “place holder.” Each system that shares the definition replaces the system symbol with a unique value during initialization.

The following terms describe the elements of system symbols:

- **Symbol Name**
  - The name that is assigned to a symbol. It begins with an ampersand (&) and optionally ends with a period (.)

- **Substitution Text**
  - The character string that the system substitutes for a symbol each time it appears. Substitution text can identify characteristics of resources, such as the system on which a resource is located, or the date and time of processing. When you define static system symbols in the IEASYMxx parmlib member (see Figure 1-7 on page 13), the substitution text can contain other static system symbols; the resolved substitution text refers to the character string that is produced after all symbols in the substitution text are resolved.
Types of system symbols

The following terms describe the types of system symbols:

**Dynamic**  A system symbol whose substitution text can change at any point in an IPL. Dynamic system symbols represent values that can change often, such as dates and times. A set of dynamic system symbols is automatically defined by z/OS; your installation cannot provide additional dynamic system symbols.

**Static**  A symbol whose substitution text is defined at system initialization and remains fixed for the life of an IPL being unique in one z/OS. One exception, &SYSPLEX, has a substitution text that can change at one point in an IPL. Static system symbols are used to represent fixed values such as system names and sysplex names.

There are two types of static system symbols:

- **System-defined**: System-defined static system symbols already have their names defined to the system. Your installation defines substitution texts or accepts system default texts for the static system symbols, which are:
  - &SYSCLONE (two or more z/OS systems in one Parallel Sysplex must never have an identical &SYSCLONE value; the default is the two first letters of the &SYSNAME)
  - &SYSNAME (identifies the z/OS name)
  - &SYSPLEX (identifies the Sysplex name)
  - &SYSR1

- **Installation-defined**: Installation-defined static system symbols are defined by your installation. The system programmer specifies their names and substitution texts in the IEASYMxx parmlib member.

Figure 1-4  Types of system symbols that can be specified

Static system symbols

z/OS substitutes text for static system symbols when it processes parmlib members, JCL, and catalog entries. For static system symbols that the z/OS provides, you can define substitution texts in parmlib or accept the default substitution texts. You can also define up to 99 additional static system symbols. You can enter the DISPLAY SYMBOLS operator command to display the static texts that are in effect for a system. See z/OS MVS System Commands, SA22-7627, for information about how to enter DISPLAY SYMBOLS.

The system symbols, listed in Figure 1-4, can be used in:

**JCL symbol**  Symbols can be defined in JCL procedures to be used with the START command. You can define JCL symbols on EXEC, PROC, and SET statements in JCL, and use them only in:

- JCL statements in the job stream
- Statements in cataloged or in-stream procedures
- DD statements that are added to a procedure

For more information about using JCL symbols, see z/OS MVS JCL Reference, SA22-7597.

**IPCS symbol**  Symbols can be use by IPCS to represent data areas in dumps that are processed with IPCS subcommands, such as SYMDEF.

For more information about using IPCS symbols, see z/OS MVS Interactive Problem Control System (IPCS) User’s Guide, SA22-7596.
Dynamic system symbols
You can specify dynamic system symbols in parmlib. However, be aware that the system substitutes text for dynamic system symbols when it processes parmlib members. For example, if you specify &HHMMSS in a parmlib member, its substitution text reflects the time when the member is processed.

This situation can also occur in other processing. For example, if you specify the &JOBNAME dynamic system symbol in a START command for a started task, the resolved substitution text for &JOBNAME is the name of the job assigned to the address space that calls the symbolic substitution service, not the address space of the started task.

Symbols reserved for system use
When you define additional system symbols in the IEASYMxx parmlib member, ensure that you do not specify the names reserved for system use.

If you try to define a system symbol that is reserved for system use, the system might generate unpredictable results when performing symbolic substitution.

In addition to the symbols reserved for system use that are shown in Figure 1-4, the following symbols are also reserved for system use:

&JDAY, &JOBNAME, &LDAY, &LHHMMSS, &LJDAY, &LMIN, &LSEC, &LTIME, &LYR2, 
LYR4, &MIN, &MON, &SEQ, &SID, &SYSNAME, &SYSPLEX, &SYSUID, &TIME, &YR2, 
&YR4, &SYSLVL
1.5 Logical parmlib and master JCL

You can concatenate up to ten data sets in SYS1.PARMLIB, in effect creating a logical parmlib. You define the concatenation in the LOADxx member of SYS1.PARMLIB or SYSn.IPLPARM. When there is more than one PARMLIB statement, the statements are concatenated together with SYS1.PARMLIB, as cataloged in the master catalog, being added at the end of the concatenation. You can also use the SETLOAD operator command to switch from one logical parmlib to another without an IPL.

The benefit of using parmlib concatenation is that it gives you greater flexibility in managing parmlib and changes to parmlib members.

Note: If you do not specify at least one PARMLIB statement in the LOADxx, the parmlib concatenation will consist of only SYS1.PARMLIB and master scheduler processing will use the IEFPARM DD statement, if there is one in the master JCL. The master JCL located in parmlib (MSTJCLxx) describes the resources to start the master scheduler address space just after the IPL conclusion. However, if there is no PARMLIB statement in the parmlib concatenation and there is no IEFPARM DD statement, master scheduler processing will use only SYS1.PARMLIB.

For more information on logical parmlib, see z/OS MVS Initialization and Tuning Reference, SA22-7592.
Master JCL

The master scheduler JCL data set (commonly called master JCL) controls system initialization and processing. It contains data definition (DD) statements for all system input and output data sets that are needed to communicate between the operating system and the primary job entry subsystem, which can be JES2 or JES3.

To change system initialization or processing, you can change the information in the member or use an alternate data set. You might need to change the master JCL at an IPL. For example, if you plan to use jobs as the source JCL for started tasks, we suggest that you modify the master JCL.

You can also modify the master scheduler JCL data set to include START commands for other subsystems, along with DD statements necessary to communicate with them. You can also delete DD statements that do not apply to your installation's interactive configuration.
1.6 Parmlib concatenation

Description and use of the parmlib concatenation

This section discusses the parmlib concatenation, its purpose, ways to control the parmlib data sets, and general syntax rules for creating most members of the data sets.

The parmlib concatenation is a set of up to ten PDS data sets defined through PARMLIB statements in the LOADxx member of either SYSn.IPLPARM or SYS1.PARMLIB. The parmlib members contain many initialization parameters in a pre-specified form in a single logical data set, thus minimizing the need for the operator to enter parameters. SYS1.PARMLIB makes the eleventh or last data set in the concatenation and is the default parmlib concatenation if no PARMLIB statements exist in LOADxx. For specific information on how to define a logical parmlib concatenation, see “LOADxx (system configuration data sets)” on page 22. The parmlib concatenation used at IPL must be a PDS. However, after an IPL you can issue a SETLOAD command to switch to a different parmlib concatenation that contains PDSEs (an enhanced version of a PDS). For information on processing of concatenated data sets see z/OS DFSMS: Using Data Sets, SC26-7410.

Refer to “PARMLIB commands” on page 34 to see the output of the D PARMLIB console command.

Parmlib contains both a basic or default general parameter list, IEASYS00, and possible alternative general parameter lists, called IEASYSaa, IEASYSbb, and so forth. Parmlib also contains specialized members, such as COMMNDxx, and IREALPaxx. Any general parameter list can contain both parameter values and “directors.” The directors (such as MLPA=01) point or direct the system to one or more specialized members, such as IREALPA01.
The IPL process always reads member IEASYS00, the default parameter list. Your installation can override or augment the contents of IEASYS00 with one or more alternate general parameter lists through specifying the SYSP parameter on the console at IPL time (it informs other suffixes for IEASYSxx). You can further supplement or partially override IEASYS00 with parameters in other IEASYSxx members or operator-entered parameters. You can specify in the IEASYSxx members the suffix of other members as follows:

- The IEASYMxx parmlib member
- The LOADxx parmlib member
1.7 Using system symbols in parmlib

Using system symbols in parmlib

After you set up parmlib for sharing, among z/OS systems of the same Sysplex, do the following to specify system symbols in parmlib definitions:

1. Know the rules for using system symbols in parmlib.
2. Determine where to use system symbols in parmlib.
3. Verify system symbols in parmlib.

Know the rules for using system symbols in parmlib

Follow these rules and recommendations when using system symbols in parmlib:

1. Specify system symbols that:
   - Begin with an ampersand (&)
   - Optionally end with a period (.)
   - Contain 1 to 8 characters between the ampersand and the period (or the next character, if you do not specify a period)

   If the system finds a system symbol that does not end with a period, it substitutes text for the system symbol when the next character is one of the following:
   - Null (the end of the text is reached)
   - A character that is not alphabetic, numeric, or special (@, #, or $)
Recommendation: End all system symbols with a period. Omitting the period that ends a system symbol could produce unwanted results under certain circumstances. For example, if the character string (2) follows a system symbol that does not have an ending period, the system processes the (2) as substring syntax for the system symbol, regardless of how you intended to use the string in the command.

2. Use a small set of system symbols so they are easy to manage and remember.

3. Code two consecutive periods (..) if a period follows a system symbol. For example, code &DEPT..POK when the desired value is D58.POK and the substitution text D58 is defined to the system symbol &DEPT.

4. When using system symbols in data set name qualifiers, keep the rules for data set naming in mind. For example, if you use SC68 as a data set qualifier, ensure that the substitution text begins with an alphabetic character.

5. Ensure that resolved substitution texts do not extend parameter values beyond their maximum lengths. For example, suppose the following command is to start CICS®:

   S CICS, JOBNAME=CICS&SC68,...

   The resolved substitution text for &SC68 cannot exceed four characters because jobnames are limited to eight characters (the four characters in CICS plus up to four character in &SC68). A substitution text of SYS1 is valid because it resolves to the jobname CICSSYS1. However, a substitution text of SYSTEM2 is not valid because it resolves to the jobname CICSSYSTEM2, which exceeds the allowable maximum of eight characters.

6. If you use &SYSCLONE, ensure that the LOADxx parmlib member indicates that the system is to check for a unique &SYSCLONE substitution text on each system.

7. If you use &SC68, ensure that its substitution text is unique on each system.

8. Do not specify system symbols in the values on the OPI and SYSP parameters in the IEASYSxx parmlib member.

9. Do not specify any system symbols in parmlib members that do not support system symbol substitution.

LOADPARM example

In the example in Figure 1-7, the LOADPARM (refer to “Initial program load (IPL)” on page 32) when IPLing SYSA is using the LOAD0A member in SYS1.IPLPARM and when IPLing SYSB the IPL is using the LOAD0B member, as follows:

- LOAD0A has the IEASYSxx suffix equal to 0A in the SYSPARM parameter.
- LOAD0B has the IEASYSxx suffix equal to 0B in the SYSPARM parameter.
- In IEASYS0A the SYSNAME value is SYSA (then &SYSNAME=SYSA).
- In IEASYS0B the SYSNAME value is SYSB (then &SYSNAME=SYSB).

Then, all the IEASYS00 parameters that are qualified by the system symbol &SYSNAME have a specific and different substitution text: SYSA for SYSA z/OS system and SYSB for the SYSB z/OS system.
1.8 Using system symbols in parmlib

- Symbols in data set names
  - SMFPRMxx parmlib member
    - SY&SYSCLONE..SMF.DATA
- Symbols when systems share the same parmlib member
  - IEASYSxx parmlib member
    - CLOCK=&SYSCLONE.
- Started task commands
  - S CICS,JOBNAME=CICS&SYSCLONE.
    - CICSSYS1 on SYS1
    - CICSSYS2 on SYS2

Figure 1-8  Examples of using system symbols in parmlib

System symbols in parmlib
System symbols offer the greatest advantage when two or more systems require different data sets, jobs, procedures, or entire parmlib members. This section provides examples of how to specify system symbols when naming certain resources in parmlib.

Data sets
A good example of using system symbols in data set names is the DSNAME parameter in the SMFPRMxx parmlib member, which specifies data sets to be used for SMF recording. Assume that each system in your sysplex requires one unique data set for SMF recording. If all systems in the sysplex use the same SMFPRMxx parmlib member, you could specify the following naming pattern to create different SMF recording data sets on each system:

SY&SYSCLONE..SMF.DATA

When you IPL each system in the sysplex, the &SYSCLONE system symbol resolves to the substitution text that is defined on the current system. For example, if a sysplex consists of two systems named SYS1 and SYS2, accepting the default value for &SYSCLONE produces the following data sets:

SYS1.SMF.DATA on system SYS1
SYS2.SMF.DATA on system SYS2

Note: The use of &SYSCLONE provides unique data set names while establishing a consistent naming convention for SMF recording data sets.
Parmlib members

You can apply the same logic to system images that require different parmlib members. For example, assume that system images SYS1 and SYS2 require different CLOCKxx parmlib members. If both systems share the same IEASYSxx parmlib member, you could specify &SYSCLONE in the value on the CLOCK parameter:

```
CLOCK=&SYSCLONE;
```

When each system in the sysplex initializes with the same IEASYSxx member, &SYSCLONE resolves to the substitution text that is defined on each system. Accepting the default value for &SYSCLONE produces the following:

```
CLOCK=S1    (Specifies CLOCKS1 on system SYS1)
CLOCK=S2    (Specifies CLOCKS2 on system SYS2)
```

Started task JCL

If JCL is for a started task, you can specify system symbols in the source JCL or in the START command for the task. You cannot specify system symbols in JCL for batch jobs, so you might want to change those jobs to run as started tasks. The reason is that in sysplex, the JCL can be interpreted in one z/OS system with specific values and executed in another z/OS with different system variables.

If a started task is to have multiple instances, determine if you want the started task to have a different name for each instance. Started tasks that can be restarted at later times are good candidates. The different names allow you to easily identify and restart only those instances that require a restart. For example, you might assign different names to instances of CICS because those instances might be restarted at later points in time. However, instances of VTAM, which are generally not restarted, might have the same name on different systems.

When you start a task in the COMMNDxx parmlib member, you can specify system symbols as part of the job name. This member has console commands to be executed automatically after the completion of the IPL and master scheduler initialization. Assume that system images SYS1 and SYS2 both need to start CICS. If both system images share the same COMMNDxx parmlib member, you could specify the &SC68 system symbol on a START command in COMMNDxx to start unique instances of CICS:

```
$ CICS,JOBNAME=CICS&SC68,...
```

When each system in the sysplex initializes with the same COMMNDxx member, &SC68 resolves to the substitution text that is defined on each system. If &SC68 is defined to SYS1 and SYS2 on the respective systems, the systems start CICS with the following jobnames:

```
CICSSYS1 on system SYS1
CICSSYS2 on system SYS2
```

Verify system symbols in parmlib

IBM provides you with tools to verify symbol usage in parmlib. The parmlib symbolic preprocessor tool allows you to test symbol definitions before you IPL the system to use them. This tool shows how a parmlib member will appear after the system performs symbolic substitution.

If you only need to verify a new parmlib member's use of the current system symbols, you can run the IEASYMCK sample program to see how the contents of the parmlib member will appear after symbolic substitution occurs.

The IEASYMCK program is located in SYS1.SAMPLIB.
1.9 Member IEASYSxx

You can specify system parameters (during IPL for z/OS customization) using a combination of IEASYSxx parmlib members and operator responses to the SPECIFY SYSTEM PARAMETERS message. You can place system parameters in the IEASYS00 member or also in one or more alternate system parameter lists (IEASYSxx) to provide a fast initialization that requires little or no operator intervention.

IEASYS00 is the most likely place to put installation defaults or parameters that will not change from IPL to IPL. The system programmer can add to or modify parameters in IEASYS00. The alternate IEASYSxx members, in contrast, should contain parameters that are subject to change, possibly from one work shift to another.

Because IEASYS00 is read automatically, the operator can respond to SPECIFY SYSTEM PARAMETERS with ENTER or U and need not enter parameters unless an error occurs and prompting ensues.

Using parameter lists
The use of system parameter lists in parmlib offers two main advantages:

- The parameter lists shorten and simplify the IPL process by allowing the installation to preselect system parameters.
- The parameter lists provide flexibility in the choice of system parameters.
You can do one of the following to specify a parameter list other than IEASYS00 for an IPL:

- Have the operator specify the suffix of an alternate IEASYSxx member by replying `SYSP=xx` in response to the SPECIFY SYSTEM PARAMETERS message.
  
  `R 00,SYSP=xx`
  
  The operator specifies this parameter to specify an alternate system parameter list in addition to IEASYS00.

- Specify one or more suffixes of alternate IEASYSxx members on the SYSPARM parameter in the LOADxx or in the IEASYMxx parmlib member.

**Overview of IEASYSxx parameters**

See *z/OS MVS Initialization and Tuning Reference*, SA22-7592 for a list of all the system parameters that can be placed in an IEASYSxx or IEASYS00 member (or specified by the operator). Detailed discussions of these parameters are provided in other sections of the IEASYSxx topic.

**Note:** PAGE and GRS are the only mandatory parameters that have no default. They must be specified.

The GRSRNL parameter is mandatory when the GRS= parameter is specified as STAR. The GRSRNL parameter is ignored when GRS=NONE (this option is not recommended).

**Specifying the list option for IEASYSxx parameters**

Certain parameters in IEASYSxx (such as CLOCK, CON, and MLPA) allow you to specify the list option (L). If you specify the L option, and message suppression is not active, then the system writes all of the statements read from the associated parmlib member to the operator's console during system initialization. If message suppression is active (the default), the system writes the list to the console log only.

To ensure that messages are not suppressed, specify an appropriate initialization message suppression indicator (IMSI character) on the LOADPARM parameter. The IMSI characters that do not suppress messages are A, C, D, M, and T.

For more information on the LOAD parameter, see the section on loading the system software in *z/OS MVS System Commands*, SA22-7627.

**Statements/parameters for IEASYSxx**

For detailed information about statements/parameters, see *z/OS MVS Initialization and Tuning Reference*, SA22-7592.
1.10 IEASYSxx and system symbols

- Understand the rules

IEASYMxx

SYMDEF(&PAGTOTL='(10,5)')

IEASYSxx

PAGTOTL=&PAGTOTL.,

- Can be specified in IEASYSxx or IEASYMxx

&SYSNAME = SYSA
&SYSCLONE = SA
&SYSPLEX = PX01

LNK=(&SYSPLEX(2:2).,03,00,L),
CLOCK=&SYSCLONE.,
PROG=&SYSNAME(1:2).,
LOGREC=&SYSNAME..LOGREC

LNK=(01,03,00,L),
CLOCK=SA,
PROG=SY,
LOGREC=SYSA.LOGERC

Figure 1-10 Specifying system symbols in IEASYSxx

IEASYSxx and system symbols

You can specify system symbols in all parameter values in IEASYSxx except in the values for the SYSP and OPI parameters and in specifying CLPA and OPI.

If you intend to use system symbols to represent parmlib member suffixes in IEASYSxx, be careful when defining, in the IEASYMxx parmlib member, parentheses (such as in the case of list notation) or commas as part of the substitution text:

- Specify system symbols only to the right of the equals sign and before the comma in the IEASYSxx notation.
- Specify only balanced parentheses in either the defined substitution text or the hard-coded values.

For example, the following notation for IEASYMxx and IEASYSxx is valid because the left and right parentheses both appear in the system symbol definition:

IEASYMxx

SYMDEF(&PAGTOTL='(10,5)')

IEASYSxx

PAGTOTL=&PAGTOTL.,

The following notation is not valid because the parentheses are split between the system symbol definition and the hard-coded definition in IEASYSxx:

IEASYMxx

SYMDEF(&PAGTOTL='10,5')

IEASYSxx

PAGTOTL=(&PAGTOTL.,
Example of using system symbols in IEASYSxx

Suppose the following system symbols have the values indicated:

\[ \text{\&SC68} = \text{SYSA} \]
\[ \text{\&SYSCLONE} = \text{SA} \]
\[ \text{\&SYSPLEX} = \text{PX01} \]

Then assume that you want to do the following in IEASYSxx:

1. Specify the LNKLISTxx member identified by the last two letters in the sysplex name and also LNKLISTxx members 03 and 00.
2. Specify the CLOCKxx member identified by \&SYSCLONE.
3. Specify the PROGxx member identified by the first two letters in the system name.
4. Specify a data set name for error recording that has the system name as a high-level qualifier.

Code IEASYSxx as follows:

\[
\begin{align*}
\text{LNK} &= (\text{\&SYSPLEX}(2:2),03,00,L), \\
\text{CLOCK} &= \text{\&SYSCLONE}, \\
\text{PROG} &= \text{\&SC68}(1:2), \\
\text{LOGREC} &= \text{\&SC68..LOGREC}
\end{align*}
\]

The values of the parameters resolve to:

\[
\begin{align*}
\text{LNK} &= (01,03,00,L), \\
\text{CLOCK} &= \text{SA}, \\
\text{PROG} &= \text{SY}, \\
\text{LOGREC} &= \text{SYSA..LOGREC}
\end{align*}
\]
1.11 IEASYMxx parmlib member

The main purpose of the IEASYMxx parmlib member is to provide a single place to specify system symbols for each system in a sysplex environment. The IEASYMxx parmlib member contains statements that do the following:

- Define static system symbols
- Specify IEASYSxx parmlib members that contain system parameters

You can apply the statements in IEASYMxx to any z/OS in your environment. Therefore, only one IEASYMxx member is required to define static system symbols and specify system parameters for all z/OS systems. There are filter statements connecting one specific z/OS with a set of static system symbols. In Figure 1-11, the static system symbol &SYS is equal to 01 if the processor is CP01 and the LPARNAME is LP01.

In IEASYMxx, you can define up to 99 additional static system symbols for each z/OS in a sysplex environment. In other words, you can define as many additional static system symbols in IEASYMxx as you like, so long as no more than 99 of those system symbols apply to a particular z/OS system at any time during an IPL.

The LOADxx parmlib member specifies the IEASYMxx member suffix that the system is to use. For information about how to specify the suffix of the IEASYMxx member in LOADxx, refer to Figure 1-12 on page 22.
1.12 LOADxx parmlib member

LOADxx (system configuration data sets)
The system must have access to a LOADxx member which specifies:

- Information about your I/O configuration as specified by IODFxx data set suffix. However, it does not contain the device number of such data set, which is indicated at IPL time.
- An alternative nucleus suffix member (IEANUC0x). The nucleus is the z/OS kernel always resident in central storage. The NUCLSTxx member is used to add and delete load modules from the nucleus region at IPL-time.
- The name and volser of the master catalog data set.
- The name of the sysplex that the IPLing system is participating in. It is also the substitution text for the &SYSPLEX system symbol.
- The IEASYMxx and IEASYSxx parmlib members that the system is to use.
- Additional parmlib data sets that the system will use to IPL. These data sets are concatenated ahead of SYS1.PARMLIB to make up the parmlib concatenation.
- The INITSQA statement allows additional SQA and ESQA storage to be reserved for IPL and NIP processing when the default amount is not sufficient.
- Filtering keywords so you can use a single LOADxx member to define IPL parameters for multiple systems. The initial values of the filter keywords (HWNAME, LPARNAME, and VMUSERID) are set at IPL to match the actual values of the system that is being IPLed.

Figure 1-12 Specifying the LOADxx parmlib member data sets
Selecting the LOADxx member

The LOADxx member suffix is selected through the use of the LOADPARM in the system control (SYSCTL) frame of the HMC system console. For information about specifying the LOADPARM, see z/OS MVS System Commands, SA22-7627. If the operator does not select a LOADxx member on the HMC system console, the system uses LOAD00.

**Note:** The system must have access to a LOADxx member.
1.13 Placement of LOADxx member

Placement of LOADxx

The suffix for the LOADxx member is indicated by the LOADPARM at the HMC console during the IPL. However, the location of the chosen LOADxx member is in one of the system data sets:

- **SYSn.IPLPARM**: SYSn.IPLPARM is an optional partitioned data set that contains LOADxx members that point to I/O definition files (IODFs) that reside on the same volume as SYSn.IPLPARM. SYSn.IPLPARM is particularly useful in a multisystem environment, as shown in Figure 1-13.

  You can use one SYSn.IPLPARM data set for each system. On each system, the SYSn.IPLPARM data set must be on the volume where the production IODF for that system resides. Observe that different z/OS may share the same IODF data set.

  For more information about the relationships between a SYSn.IPLPARM data set and its associated IODFs, see z/OS MVS System Data Set Definition, SA22-7629.

  **Note**: This SYSn.IPLPARM volume should contain only one SYSn.IPLPARM data set and its associated IODFs. (The character \(n\) is a single numeral, 0 through 9.)

- **SYS1.PARMLIB**: The LOADxx member can also be allocated in SYS1.PARMLIB. During IPL, the system looks for LOADxx in the following order:

  1. SYS0.IPLPARM through SYS9.IPLPARM on the IODF volume
2. SYS1.PARMLIB on the IODF volume
3. SYS1.PARMLIB on the SYSRES volume

Do not create a SYSn.IPLPARM data set unless it contains the LOADxx member that is used to configure your system. When the system finds either SYSn.IPLPARM or SYS1.PARMLIB, it expects to find a LOADxx member in the data set. If the LOADxx member specified on the LOAD parameter is not in the data set, the system loads a wait state and the IPL fails.

The NUCLSTxx member must reside in the same data set as the LOADxx member. This member can reside in either SYS1.PARMLIB or SYSn.IPLPARM, depending on how the installation defined its I/O configuration.

Member SYSCATLG of SYS1.NUCLEUS also may contain a pointer to the master catalog. However, IBM recommends that you use the SYSCAT statement of the LOADxx member of SYS1.PARMLIB or SYSn.IPLPARM to identify the master catalog.

*Figure 1-14  Ways to control parmlib members*

### Controlling parmlib

A parmlib concatenation allows you to have more flexibility in managing parmlib members and changes to parmlib members. To control parmlib and ensure that it is manageable, you should consider the following:

- Use the ability to have up to 10 installation-defined parmlib data sets to separate your parmlib members along organization or function lines and use appropriate RACF security for each data set.
- Include members with installation changes in one of the 10 installation-defined parmlib data sets to avoid having the member overlaid by IBM maintenance on SYS1.PARMLIB.
- Use an installation-defined parmlib data set to contain any parmlib members to be used on test systems. They can be included in front of your *standard* parmlib concatenation without forcing changes to the *standard* parmlib concatenation.
- Delete unsupported parameters and members. Because most components treat unsupported parameters from previous releases as syntax errors, you should probably remove the old parameters or build parmlib from scratch. This action will minimize the need for operator responses during an IPL. Then, you can save space by removing unsupported members.
- Use the parmlib members for the appropriate functions. For example, use COMMNDxx to contain commands useful at system initialization. Use IEACMDxx for IBM-supplied commands. Use IEASLPxx for SLIP commands. See each member for further information.
Update parmlib with new or replacement members as you increase your experience with new releases.

Keep track of which parameters are included in particular parmlib members. This bookkeeping is necessary for two reasons:

a. The system doesn't keep track of parmlib members and their parameters.

b. The default general parameter list IEASYS00 is always read by IPL process and master scheduler initialization.

The parameters in IEASYS00 can be overridden by the same parameters when they are specified in alternate general lists, such as IEASYS01, or IEASYS02. Then, certain parameters, such as FIX, APF, and MLPA, direct the system to particular specialized members (in this example, IEAFIXxx, and IEALPAxx).

The installation should keep records of which parameters and which values are in particular members, and which general members point to which particular specialized members (COMMNDxx, IEALPAxx, and so forth). A grid or matrix for such bookkeeping is very helpful.

Allocate sufficient space for parmlib. One way to estimate space is to count the number of 80-character records in all members that are to be included in one parmlib data set and factor in the block size of the data set. Then add a suitable growth factor (for example, 100 to 300 percent) to allow for future growth of alternate members. To recapture space occupied by deleted members, use the `compress` function of IEBCOPY. However, should the data set run out of space, you may copy the members to a larger data set, create a new LOADxx member in which you replace the PARMLIB statement for the full data set with a PARMLIB statement for the new larger data set, and then issue a `SETLOAD` command to switch to the concatenation with the new data set.

Ensure EXITxx and GTFPARM reside in SYS1.PARMLIB since they can only be accessed from SYS1.PARMLIB.

Decide which volume(s) and device(s) should hold the parmlib concatenation. The data set must be cataloged, unless it resides on SYSRES or its volume serial number is included on the PARMLIB statement in LOADxx. The data set could be placed on a slow or moderate speed device. For information about the placement of parmlib data sets and the IODF data set, see `z/OS MVS System Data Set Definition, SA22-7629`.

Use a security product (like RACF) to protect the data sets. The purpose is to preserve system integrity by protecting the appendage member (IEAAPP00) and the authorized program facility members (IEAAPFxx and PROGxx) from user tampering.

Figure 1-15 ISPF SYS1.PARMLIB member list

SYS1.PARMLIB member list

Figure 1-15 shows a partial display of the SYS1.PARMLIB members using ISPF to see the members.

The following general syntax rules apply to the creation of most parmlib members. Exceptions to these rules are described under specific members. The general rules are:

- Logical record size is 80 bytes.
- Block size must be a multiple of 80.
- Any columns between 1 and 71 may contain data.
- Statements are entered in uppercase characters.
- Suffix member identifiers can be any combination of A to Z and 0 to 9, though some member identifiers may allow other characters.
- Columns 72 through 80 are ignored.
- Continuation is indicated by a comma followed by one or more blanks after the last entry on a record.
- Leading blanks are suppressed. A record therefore need not start at a particular column.
- Suffix member identifiers (such as LNK=A2) can be any alphanumeric combination.
- Comments are most often indicated by using /* and */ as the delimiter in columns 1–71, for example, /*comment*/.
1.16 Initialization of z/OS

The IPL program loads the z/OS kernel and the Nucleus Initialization Program (NIP) from the data set SYS1.NUCLEUS located in the IPL device. After that the CPU control is passed to NIP.

During the NIP processing, it prompts the operator to provide system parameters that control the operation of MVS. The system also issues informational messages that inform the operator about the stages of the initialization process.

The LOADxx parmlib member allows your installation to control the initialization process. For example, in LOADxx, you specify the suffixes for IEASYSxx or IEASYMxx members that the system is to use; the system does not prompt the operator for system parameters that are specified in those members. Instead, it uses the values in those members.

The definition of these parameters are discussed later in this chapter.
1.17 Types of IPLs

- Cold start
  - Loads PLPA - (CLPA)
- Quick start
  - No reload of PLPA - (CVIO)
- Warm start
  - No reload of PLPA

Message to operator and a possible response

IEA101A  SPECIFY SYSTEM PARAMETERS
R 00,SYSP=xx,CLPA
R 00,SYSP=xx,CVIO

Figure 1-17  The three types of IPLs and the operator response

Types of IPL
There might be some terms in this discussion that are unfamiliar to you (like LPA, SQA, VIO, and so forth). The objective of this section is to condense the IPL types and process (shown in the “Initial program load (IPL)” on page 32) in order to give you an overview of the IPL and its interactions with the operator. The new terms mentioned here are more fully explained as we go through the rest of the discussion.

Pageable Link Pack Area (PLPA) is a virtual storage area where IPL pre-loads key programs (load modules) that will have a high probability of being executed when the system reaches the steady state. Virtual I/O is a z/OS technique to speed up, through virtualization, the processing of temporary files, keeping them in local page data sets.

Depending on the level of customization, an IPL can bring up many different configurations, but there are only three basic types of IPL:

- Cold Start
  Any IPL that loads or reloads the PLPA to the PLPA page data set and does not preserve VIO data sets. The first IPL after system installation is always a cold start because the PLPA must be initially loaded. At the first IPL after system installation the PLPA will automatically be loaded from the LPALST concatenation. The page data sets for this IPL are those specified in IEASYSxx, plus any additional ones specified by the operator. Subsequent IPLs need only be cold starts if the PLPA has to be reloaded either to alter its contents (a new program, for example) or to restore it (the PLPA page data set) when it has been destroyed.
The PLPA needs to be reloaded:

- At the first IPL after system initialization, when the system loads it automatically.
- After modifying one or more programs (load modules) in the LPALST concatenation.
- After the PLPA page data set has been damaged and is therefore unusable, so its contents must be restored. The PLPA can be reloaded by responding CLPA (Create Link Pack Area) to the SPECIFY SYSTEM PARAMETERS prompt.

**Quick Start**

Any IPL that does not reload the PLPA and does not preserve VIO data sets. The system re-creates page and segment tables to match the in-use PLPA in PLPA page data set. The PLPA from the previous IPL can be used without reloading it from the LPALST concatenation. A Quick Start can be initiated by replying CV10 (Clear VIO) to the SPECIFY SYSTEM PARAMETERS prompt.

**Warm Start**

Any IPL that does not reload the PLPA and preserves journaled VIO data sets. The operator does not enter CLPA or CV10 at the SPECIFY SYSTEM PARAMETERS prompt. Any definitions of existing page data sets as non-VIO local page data sets are preserved.

Due to the high speed of DASD devices there is not much difference (time wise) between Cold Start and the others.

The expressions Cold Start and Warm Start also apply to the JES (JES2 or JES3) initialization, referring to whether the JES spool data set contents are going to be kept or not.

**System parameters prompt**

If the LOADPARM (shown in Figure 1-18 on page 32) has been set to indicate the operator should be prompted for system parameters (A, P, S or T), NIP issues the following prompt on the NIP console:

```
IEA101A  SPECIFY SYSTEM PARAMETERS
```

At this point, the operator can respond in one of a number of ways:

- Pressing Enter will cause the system to use the parameters coded in parmlib (IEASYS00).
- Entering `SYSP=xx` will cause the parameters in parmlib (IEASYSxx) to be used.
- Entering multiple IEASYSxx members, `SYSP=(xx,yy,...)`, for multiple concatenations to be used.

Specifying any of the individual parameters that appear in IEASYSxx causes these parameters to be used instead of the ones coded in IEASYSxx except PAGE parameters. If multiple IEASYSxx members are searched, the system always reads IEASYS00 first, followed by the additional ones you specify. If the same parameters are found in one or more IEASYSxx members, the latest overriding parameter is used.

**PAGE parameters**

The PAGE parameter allows the installation to name page data sets as additions to existing page data sets. The maximum number of page data sets is 256, which includes the optional page data set specified by the DUPLEX parameter (not recommended). The system determines which page data sets to use by merging information from three sources: IEASYS00, IEASYSxx, and the PAGE parameter.

During system initialization, the system first uses the list of page data sets specified on the PAGE parameter of the IEASYS00 parmlib member. It then uses any other IEASYSxx parmlib member (identified via the SYSP=xx parameter). The IEASYSxx PAGE data set name list overrides the one in IEASYS00.
1.18 Initial program load (IPL)

The IPL process
An initial program load (IPL) is the act of loading a copy of the operating system from disk into the CPU's central storage and executing it. Not all disks attached to a CPU have loadable code on them. A disk that does is generally referred to as an “IPLable” disk, and more specifically as the SYSRES volume. IPLable disks will contain a bootstrap module at cylinder 0, track 0, block 0. At IPL, this bootstrap is loaded into storage at real address zero and control is passed to it. The bootstrap then reads the IPL control program IEAIPL00 (also known as IPL text) and passes control to it. This in turn starts the more complex task of loading the operating system and executing it. Attempts to IPL from a disk that does not contain IPL text results in a wait state error condition.

IEAIPL00 program logic
IEAIPL00 prepares an environment suitable for starting the programs and modules that make up the z/OS. First, it clears central storage to zeros before defining storage areas for the master scheduler address space. It then locates the IEANUC0x member in SYS1.NUCLEUS data set on the SYSRES volume and loads a series of programs from it known as IPL Resource Initialization Modules (IRIMs). These IRIMs will then start to construct the normal operating system environment of control blocks and subsystems that make up a z/OS system. Some of the more significant tasks performed by the IRIMs are to:

- Read the LOADPARM information entered on the HMC hardware console at the time the IPL command was executed.
- Search the volume specified in the LOADPARM as containing the IODF data set for the LOADxx member; the value of xx is also taken from the LOADPARM. IRIM first attempts
to locate LOADxx in SYS0.IPLPARM. If this is unsuccessful, it looks for SYS1.IPLPARM, and up to and including SYS9.IPLPARM. If, at this point, it still has not been located, the search continues in SYS1.PARMLIB. When a LOADxx member has been successfully located, it is accessed looking for the following information: IEANUC0x suffix (unless overridden in LOADPARM), the master catalog name, and the suffix of the IEASYSxx member.

- Load the z/OS nucleus.
- Initialize virtual storage in the master scheduler address space for the System Queue Area (SQA), the Extended SQA (ESQA), the Local SQA (LSQA), and the Prefixed Save Area (PSA). At the end of the IPL sequence, the PSA replaces IEAIPL00 code at real storage location zero.
- Initialize real storage management, including the master scheduler segment table entries for common storage areas, and the page frame table.

The last of the IRIMs then loads the first part of the Nucleus Initialization Program (NIP), which then invokes the Resource Initialization Modules (RIMs), one of the earliest of which starts up communications with the z/OS console.

The load parameter (LOADPARM)

The most basic level of control is through the Load Parameter (LOADPARM). This is an eight-character value made up of four fields that the IPL program refers to during the IPL process, causing it to take the specified actions. The LOADPARM is made up of the following components:

- **IODF ccuu**
  
  The IODF device number. This is also the device on which the search for the LOADxx member of SYSn.IPLPARM or SYS1.PARMLIB begins. The first four characters of the LOADPARM specify the hexadecimal device number for the device that contains the I/O Definition File (IODF) VSAM data set. If you do not specify the device number, the hardware uses the device number of the system residence (SYSRES) volume.

- **LOADxx**
  
  The xx suffix of the LOADxx parmlib member. The LOADxx member contains information about the name of the IODF data set, which master catalog to use, which IEASYSxx/IEASYMxx members of SYS1.PARMLIB to use, and parmlib concatenation data sets. The default for the LOADxx suffix is zeroes. The IPL program reads the LOADxx and NUCLSTxx members from SYSn.IPLPARM or SYS1.PARMLIB on the IODF device specified in the LOADPARM (or the SYSRES volume, if no volume is specified). Later, NIP opens the master catalog to locate the volumes of all data sets to be concatenated with the SYS1.PARMLIB. This parmlib could be different from the SYS1.PARMLIB to which the LOAD parameter points.

- **IMSI x**
  
  The prompt feature character specifies the prompting and message suppression characteristics that the system is to use at IPL. This character is commonly known as an initialization message suppression indicator (IMSI). Some IMSI characters suppress informational messages from the system console, which can speed up the initialization process and reduce message traffic to the console. It can also cause you to miss some critical messages, so you should always review the hardcopy log after initialization is complete. One of the reasons to select prompting suppression is to enable unattended operation.

- **Alt Nuc x**
  
  The last character specifies the alternate nucleus identifier (0–9). If you do not specify an alternate nucleus identifier, the system loads the standard (or primary) nucleus (IEANUC01), unless the NUCLEUS statement is specified in the LOADxx member.

*Figure 1-19 Commands to display parmlib information after IPL*

**Parmlib commands**

The use of commands enables installations to display the current logical parmlib, display general IPL information, and change the current logical parmlib settings.

The commands are:

- **DISPLAY PARMLIB**
  
  This command displays the logical parmlib setup for the IPLed system. The output of this command includes the parmlib data set names and volsers that were defined by LOADxx PARMLIB statements, and if used, master JCL IEFPARM DD statements. When the errors option on the command is used, the display shows any parmlibs that were defined in LOADxx but were not found. This command is only valid before a SETLOAD command is issued. A sample output is shown in the Figure 1-19, where the flag S means defined at LOADxx and flag D means defined by default.

- **DISPLAY IPLINFO**
  
  This command displays the general IPL information used by the system. The output includes the date and time of the IPL, release level, LOADxx information, and what IEASYSxx and IEASYMxx parmlib members were used. A sample output of the command is shown in Figure 1-19.
1.20 Parmlib commands (continued)

The SETLOAD command allows the installation to dynamically change a parmlib concatenation without having to IPL. It specifies the LOADxx member that contains the PARMLIB statements to use. The syntax of the command is as follows:

```
SETLOAD xx,PARMLIB[,{DSNAME|DSN}=dsn][,{VOLUME|VOL|VOLSER}=vol]
```

Where:

- **xx** - Specifies the one or two character suffix used to identify the LOADxx member that you want to process.
- **PARMLIB** - Specifies that the system is to process the PARMLIB statements in the LOADxx member according to the filter parameters (HWNAME, LPARNAME, VMUSERID). For more information on filter parameters, see the LOADxx member in z/OS MVS Initialization and Tuning Reference, SA22-7592.
- **DSNAME** or **DSN** =dsn - Specifies the 1 to 44 character name of the data set where the LOADxx member resides. The default is to locate the LOADxx member specified in a data set within the existing parmlib concatenation.
- **VOLUME** or **VOL** or **VOLSER** =vol - Specifies the 1 to 6 character serial number identifier of the volume where the specified data set resides.

A sample output of the SETLOAD command is shown in Figure 1-20.

```
SETLOAD R2,PARMLIB,DSN=SYS0.IPLPARM
```

```

```

Figure 1-20 Changing parmlib concatenations with the SETLOAD command

Parmlib commands

The SETLOAD command allows the installation to dynamically change a parmlib concatenation without having to IPL. It specifies the LOADxx member that contains the PARMLIB statements to use. The syntax of the command is as follows:

```
SETLOAD xx,PARMLIB[,{DSNAME|DSN}=dsn][,{VOLUME|VOL|VOLSER}=vol]
```

Where:

- **xx** - Specifies the one or two character suffix used to identify the LOADxx member that you want to process.
- **PARMLIB** - Specifies that the system is to process the PARMLIB statements in the LOADxx member according to the filter parameters (HWNAME, LPARNAME, VMUSERID). For more information on filter parameters, see the LOADxx member in z/OS MVS Initialization and Tuning Reference, SA22-7592.
- **DSNAME** or **DSN** =dsn - Specifies the 1 to 44 character name of the data set where the LOADxx member resides. The default is to locate the LOADxx member specified in a data set within the existing parmlib concatenation.
- **VOLUME** or **VOL** or **VOLSER** =vol - Specifies the 1 to 6 character serial number identifier of the volume where the specified data set resides.

A sample output of the SETLOAD command is shown in Figure 1-20.

```
SETLOAD R2,PARMLIB,DSN=SYS0.IPLPARM
```

Figure 1-21 Displaying the parmlib members in use after a setload command

Use of SETLOAD command

The sample output shown in Figure 1-21 is a result after the SETLOAD command was issued.

The second display shows the output of a DISPLAY PARMLIB command after an IPL had taken place using LOADR2. PARMLIB statements were specified in LOADR2. Note the difference in the FLAGS column shown in the figure.

The FLAGS describe how the parmlibs were specified:

- S denotes the LOADxx PARMLIB statement.
- D denotes the default (SYS1.PARMLIB).
1.22 Catalogs

A catalog is a z/OS VSAM data set that contains information about other data sets, such as the volume serial (the name of the volume containing the data set). It provides users with the ability to locate a data set by name, without knowing where the data set resides. By cataloging data sets, your users need to know less about your DASD storage setup. Thus, data can be moved from one device to another, without requiring a change in JCL DD statements which refer to an existing data set.

Cataloging data sets also simplifies backup and recovery procedures. Catalogs are the central information point for VSAM data sets; all VSAM data sets must be cataloged. In addition, all SMS-managed data sets (data sets whose performance and availability are managed by the SMS system component) must also be cataloged.

Functionally, the catalogs are divided into master (mastercat) and user catalogs (usercat). Mastercat has z/OS system data set information and pointers to usercats based on the data set name high-level qualifier of the data set being located. Usercats contain non-z/OS data set information. For each high-level qualifier associated with a specific usercat, the installation defines one alias in the mastercat pointing to the usercat. There is no physical difference between a mastercat and usercats.

Using indirect catalog entries
When sharing the mastercat, it might be desirable for an alias to reference a different data set or usercat, depending on the z/OS it is accessed from.
To implement such facility two functions are implemented:

- Indirect volume serial support allows the system to dynamically resolve volume and device type information for non-VSAM, non-SMS managed data sets that reside on the SYSRES volume when accessed through the catalog (the VOLSER information is ****** meaning the current Sysres of this z/OS). This allows you to change the Volser or the device type of the SYSRES without also having to re-catalog the non-VSAM data sets on that volume.

- The extended indirect volume serial support allows catalog entries to be resolved using system symbols. You can define an alias for a usercat or a non-VSAM data set where the catalog name or the non-VSAM data set name contains system symbols. This name is resolved at the time that alias entry is referenced, rather than when it is defined. Therefore, you can have multiple levels of z/OS data sets residing on multiple sets of volumes with different names and device types, and use them with the same master catalog.

For more information on indirect volume serial support, see z/OS MVS Initialization and Tuning Reference, SA22-7592.

**Catalog management**

Ensuring that your catalogs are effectively managed is a crucial aspect of DASD management. Some of the most common catalog management tasks that a system programmer may have are:

- Defining and maintaining the master catalog. A general recommendation is that every z/OS has its own master catalog connected to shared (between other z/OS systems) user catalogs. This improves continuous availability by preventing the master catalog from being a single point of failure.

- Defining the alias and user catalog. Try to distribute the load of the user catalogs; a criteria could be one user catalog per data sets application.

- Protecting the catalogs with RACF.

- Cleaning up catalogs.

- Backing up catalogs and performing catalog recovery using products such as ICFRU.
1.23 Separating data from software

When you install z/OS in your DASD volumes it is recommended to separate your data from your z/OS software. With this procedure you eliminate many tasks that would otherwise need to be performed each time you upgrade or replace your z/OS software. One effective way to achieve this is to use dedicated pools of DASD volumes for each.

The kinds of data you should separate from z/OS software are:

- Customization data, including most system control files such as SYS1.PARMLIB
- Non-IBM software
- IBM non-z/OS products, for example CICS and DB2®
- User-defined exits
- User data

Your goal is to make it easier to replace the volumes that contain z/OS software, which allows you to keep the other software and data you will need to use with z/OS across migrations.
1.24 Placing data sets on specific volumes

Some SYSRES volume types, such as the 3390-3, are not big enough to hold all the target libraries for a z/OS system. Target libraries are the ones containing the z/OS data and programs that will be used when running the system. Therefore, you have to move some data sets to SYSRES logical extension volumes (or overflow volumes). Observe that today we have up to 54 MB per volume. The considerations you should take into account for placing data sets on specific volumes are:

- Your ability to use a system (or subsystem) replacement
- Data set and system availability
- System performance
- System cloning and servicing techniques
- Sysplex/multisystem operations
- Sharing data sets
- Backup and recovery
- Disaster recovery

Figure 1-24 Where to place data sets
With these considerations in mind, you should determine which data sets to place on each volume based on data set type and not based on element, feature, or product. There are basically five types of data sets, each of which can be placed on a separate (logical) 3390 volume:

- SMP/E global-shared data sets. SMP/E is the z/OS component in charge of maintaining the z/OS, other products and subsystem software.
- Target libraries (TLIBs) for product sets.
- Distribution libraries (DLIBs) for product sets. These are the libraries copied directly from tapes or from the network.
- z/OS managed data sets.
- Parallel Sysplex-related data sets.

**SMP/E global shared data sets**

These data sets should be placed on a volume shared by all z/OS systems in the complex that need SMP/E global information. Sharing these data sets provides for easy backup and recovery. The recommended types of data sets for this volume are:

- SMP/E global CSI
- SMPPTS
- SMP/E global logs (SMPLOG and SMPLOGA)
1.25 The TLIBs volumes

- TVOL1
- TVOL2 - n
- HFS Target Volume
- Licensed Product Target Volume
- Vendor Product Target Volume
- Subsystem Target Volume

Figure 1-25 Target libraries

Target libraries (TLIBs) for product sets
These target libraries spread across several volumes, from primary to secondary volumes:

- **Primary target volume (TVOL1)** - The TVOL1 is the first target library volume and the SYSRES (IPL) volume; it contains many of the z/OS target libraries. Make sure you leave enough free space to allow for future growth. The recommended types of TVOL1 data sets are:
  - Load libraries - data sets containing load modules
  - Change migration libraries - used during migration from one level of software to another
  - Help libraries - data sets that contain help information
  - Panel libraries - data sets that contain ISPF panels
  - Message libraries - z/OS libraries that contain ISPF messages and MMS source messages
  - Skeleton libraries - z/OS libraries that contain ISPF skeletons
  - Table libraries - z/OS libraries that contain ISPF tables
  - Fixed-block CLIST and EXEC libraries - data sets that contain CLIST and REXX™ EXECs
  - Data libraries - z/OS libraries that contain data parts which include workstation information, header files, or other various types of data
  - SMP/E-managed PARMLIB - the data set that is pointed to by the PARMLIB DDDEF, which will be used to store parmlib members supplied by products you install
– SMP/E-managed PROCLIB - the data set that is pointed to by the PROCLIB DDDEF, which will be used to store JCL procedures supplied by products you install

► **Secondary target volumes (TVOL2–TVOLn)** - The TVOL2 through TVOLn are volumes used for data sets that do not fit on TVOL1. They are for the z/OS product set and the recommended types of TVOL2 through TVOLn data sets are:

– Fixed-block CLIST and EXEC libraries - used only if variable-block CLIST and EXEC libraries were used on TVOL1
– Sample and JCL libraries - z/OS libraries that contain samples, header files, and JCL jobs
– Source libraries - z/OS libraries that contain source code
– Macro libraries - z/OS libraries that contain assembler macros, header files, and other information identified in SMP/E as the element type MACRO
– Workstation libraries - can be combined with the data libraries
– Softcopy libraries into which SMP/E installs - z/OS libraries that contain books, bookshelves, and book indexes.
– Font and printing libraries - z/OS libraries that contain fonts and data sets required for printing.
– Flat files that SMP/E cannot manage - interface repositories and so forth, excluding books.
– SMP/E target CSI
– SMP/E target data sets - including SMPLTS, SMPMTS, SMPSTS, and SMPSCDS.
– User catalog for the SMP/E target CSI and MVS-supplied data sets

► **HFS target volume** - Recommended types of data sets (file systems) for this volume are:

– HFS data sets for z/OS elements or features that install into an HFS
– Any non-z/OS HFS data set, except those containing customization data

► **Licensed product target volume** - The libraries on this volume consist of the licensed product set that you might not have in a system-replacement order and you want to keep separate. The recommended types of data sets for this volume are:

– Licensed program target libraries
– SMP/E target CSI
– SMP/E target data sets: SMPLTS, SMPMTS, SMPSTS, and SMPSCDS
– User catalog where all the licensed program libraries and the SMP/E target CSI are cataloged

► **Vendor product target volume** - The libraries on this volume consist of the vendor product set that you might not have in a system-replacement order and you want to keep separate. The recommended types of data sets for this volume are:

– Vendor target libraries
– SMP/E target CSI
– SMP/E target data sets: SMPLTS, SMPMTS, SMPSTS, and SMPSCDS
– User catalog where all the vendor product target libraries including the SMP/E target CSI are cataloged

► **Subsystem target volume** - The libraries on this volume consist of the subsystem product sets (for example, CICS, DB2, IMS™, or NCP). The recommended types of data sets for this volume are:

– Subsystem target libraries
– Alternate subsystem SMP/E global CSI, if applicable
– SMP/E target CSI
– SMP/E target data sets: SMPLTS, SMPMTS, SMPSTS, and SMPSCDS
– User catalog where the subsystem targets libraries including SMP/E CSIs are cataloged
1.26 The DLIB volumes

- **DLIB Vol for TVOL1, TVOL2 - TVOLn, HFS**

- **DLIB Vol for Licensed Products**

- **DLIB Vol for Vendor Products**

- **DLIB Vol for Subsystems**

---

**Distribution libraries (DLIBs) for product sets**

You should place data sets on the DLIB volumes wherever they fit. However, keep in mind how other systems use the distribution libraries when you are deciding where to place them. There are cases where you don't want or need a set of distribution libraries available on certain packs, for example having multiple target zones connect to a DLIB zone. The DLIB volumes, like the target volumes, can be divided into primary and secondary volumes:

- **DLIB volumes for TVOL1, TVOL2 through TVOLn, and HFS**
  
  These distribution libraries are the ones that are placed by ServerPac for your z/OS product sets. By keeping the distribution libraries on the same volumes it will be easier to avoid overlaying data sets.

- **DLIB volumes for licensed products**
  
  These are the distribution libraries that correspond to the target libraries for the licensed product set. These are data sets that would not be overlaid in a system replacement.

- **DLIB volume for vendor products**
  
  These are the distribution libraries that correspond to the target libraries for the vendor product set. These are data sets that would not be overlaid in a system replacement.

- **DLIB volumes for subsystems**
  
  These distribution libraries are the ones that are placed by ServerPac for subsystem product sets. Keeping the distribution libraries on the same volumes makes it easier to avoid overlaying data sets.
1.27 The z/OS image-related volumes

- Page data set volume 1
- Page data set volume 2 through n
- HFS customization volume

Figure 1-27 Volumes containing non-shareable system information

Image-related data sets
These data sets contain non-shareable system image information. Although the recommendation is that they be put on separate volumes, if DASD space is scarce you can combine them at the expense of performance or availability, or both. The image-related data sets are placed in the following recommended volumes:

- **Page data sets volume 1** - The recommended types of data sets for this volume are:
  - PLPA (one-cylinder allocation)
  - COMMON

Note: Unless your system is central-storage constrained, and has significant PLPA paging activity, there is little or no performance impact to combining the PLPA and COMMON page data sets. The PLPA data set should be allocated first, as a one-cylinder data set, with the COMMON data set allocated second, immediately following the PLPA data set on the same volume. The size of the COMMON data set should be large enough to contain both PLPA and COMMOND pages.

This causes the vast majority of PLPA pages to be written to the COMMON page data set during the IPL. This allows the z/OS to use the chained CCWs within a single data set and improves performance when both data sets are on the same volume.

The message (**ILR005E PLPA PAGE DATA SET FULL, OVERFLOWING TO COMMON DATA SET**) during IPL can be ignored when the PLPA and COMMON page data sets are on the same volume.
- **Page data set volumes 2 to n** - The recommended types of data sets for these volumes are:
  - Local Page data set (never define two local page data sets in the same volume)
  - SMF
  - RMF reporting
  - STGINDEX data set (if used)
  - Image-related LOGREC data set (if used)

- **HFS customization volume** - This is an installation-maintained volume that contains data sets that will not be overlaid by system replacement. This volume is separate from the HFS target volume because it contains unshareable HFS files that will generally need to be mounted MODE(RDWR). The recommended types of data sets for this volume are:
  - HFS data sets that must be in write mode (for instance, /tmp, /etc, /dev, /u) and that contain customized information.
  - User catalog where the HFS data sets are cataloged.
1.28 The cluster-related volumes

- Master catalog volume
- JES Checkpoint volume
- JES Spool volume
- Sysplex volume 1
- Sysplex volume 2
- Softcopy volumes

Figure 1-28 Volumes containing shareable data sets

Cluster-related data sets

*Cluster* in this case can be translated to Parallel Sysplex.

These are shareable data sets used in a multisystem environment. Cluster-related data sets should use system symbols in their names for easier maintainability. While all cluster-related data sets can be combined on the same volume, it is usually preferable to separate certain data sets from others for performance or availability reasons. You can group the cluster-related data sets into the following volumes:

- **Master catalog volume** - The recommended types of data sets for this volume are:
  - Master Catalog
  - BROADCAST data set
  - Customer parmlib concatenation (not the SMP/E DDDEFed PARMLIB)
  - Customer proclib concatenation (not the SMP/E DDDEFed PROCLIB)
  - UADS data set (if used)
  - VTAMLST data set
  - SMS control data sets (ACDS, SCDS, and COMMDS), HSM, RMM, and so forth
  - APPC VSAM data set
  - System control files (TCPI/P configuration and so forth)
  - Primary RACF database
  - IODF data set
  - SYS0.IPLPARM
  - UCATs
  - SYS1.DDIR sysplex dump directory data set
– DAE data set

► **JES2 checkpoint volume** - For maximum performance and reduced contention, place the primary JES2 checkpoint data set on its own dedicated volume. The JES2 checkpoint primary data set may be on a Coupling Facility.

► **Sysplex-related volume 1** - The recommended types of data sets for this volume are:
  – Sysplex couple data set primary
  – CFRM couple data set alternate
  – ARM couple data set primary
  – WLM couple data set primary
  – LOGR couple data set primary
  – OMVS couple data set primary

**Note:** The CFRM primary and SYSPLEX primary should be on different volumes attached to different control units. All other primary couple data sets can reside on the same volume, and all other alternate couple data sets can reside on a different volume.

► **Sysplex-related volume 2** - The recommended types of data sets for this volume are:
  – Sysplex couple data set alternate
  – CFRM couple data set primary
  – ARM couple data set alternate
  – WLM couple data set alternate
  – LOGR couple data set alternate
  – OMVS couple data set alternate
  – Secondary RACF database

► **Softcopy volume** - This volume holds softcopy books and related data sets. The recommended types of data sets for this volume are:
  – Books
  – Bookshelves
  – Book indexes

Many volumes on your system contain data sets that are not supplied by ServerPac. Keeping such volumes separate from those that ServerPac will replace, or that you will replace when migrating the new system to other system images, makes it easier to prevent overlaying data sets that you want to keep.

For more information on data set placement, see *z/OS and z/OS.e Planning for Installation*, GA22-7504.
1.29 Naming conventions for data sets

Choosing the right naming conventions for system data and software data sets can save you considerable time during installation and migration.

Some data sets are associated with only one system in a multisystem environment. Choose names for these data sets that reflect the name of the specific system. Names of system operational data sets, such as page and swap data sets, should include the system name. You can accomplish this using the IBM-supplied system symbol \&SYSNAME.

Using symbolic substitution involves carefully establishing naming conventions for data sets such as parmlib and proclib members, system images, HCD definition, and so forth. Remember that once your system goes into production with a set of naming conventions, you cannot easily change them.

IBM has been removing the level-dependent qualifier (such as V1R1M0) from default data set names for z/OS elements in order to ease your migration to a new z/OS release. This preserves much of your existing JCL, system procedures, parmlib and other system control file contents, and security system definitions across upgrades, saving you time and reducing the opportunity for error because updates will be limited to just the data sets in which the low-level qualifiers were changed.
1.30 DASD space utilization and performance

- Non-RECFM U Data Sets
  - Use System Determine Block Size, BLKSIZE=0
- RECFM U Data Sets
  - Use BLOCKSIZE=32760
- UADS Data Sets
  - Same block size as the currently used
- Font Libraries
  - Use BLOCKSIZE=12288

**Figure 1-30 Determining space utilization for data sets**

**DASD space utilization and performance**

The space required by system data and software data sets, except for PDSE data sets, is affected by the block sizes you choose for those data sets. Generally, data sets with larger block sizes use less space to store the same data than those with smaller block sizes because there are fewer gaps between the larger physical blocks.

One exception to this general rule is for 3390 DASD data sets. They should not be allocated with block sizes larger than half the track length of the DASD they are allocated on. Doing so will cause considerable DASD space to be wasted because current DASD track lengths are less than twice the maximum block size of 32760 bytes, as allowed by DASD access methods.

**System-determined block size**

Generally, system-determined block sizes are the best choice for block size for fixed block (FB, all the logical records with the same size), variable block (VB logical records and physical records with variable size), and variable block spanned (VBS on logical record can span several same size physical records) record format data sets. You should use system-determined block size for all z/OS data sets with these record formats except those for which IBM specifically recommends other block sizes. One way to do this is by specifying BLKSIZE=0 in the DCB parameter of a DD statement when allocating new data sets using JCL. For more information, see z/OS MVS JCL Reference, SA22-7597.
Data sets with undefined (U, just one variable size logical record per physical block) record formats do not follow the same rules as those with other record formats. In particular, most load libraries in partitioned data sets (not PDSEs) require less space and offer better performance at increasing block sizes right up to the block size limit of 32760 bytes. This is because the program management binder, linkage editor, and IEBCOPY's COPYMOD command use the data set block size only to set the maximum block length they use.

**Load libraries**

Allocate all load module (programs) libraries, such as SYS1.LINKLIB, using a maximum block size of 32760 bytes.

For most efficient use of DASD, it is recommended that you allocate z/OS data sets using the following block sizes:

- Use the system-determined block size for most non-RECFM U data sets.
- For RECFM U data sets, use BLKSIZE=32760.
- For UADS data sets for TSO/E, use the same block size you currently use to allocate a new one. Do not use system-determined block size because this will result in very poor DASD space utilization.
- You should not use the system-determined block size for font libraries either. The correct block size for the font libraries is 12288.

For more information on the usage of system-determined block size, see *z/OS DFSMS: Using Data Sets*, SC26-7410.
1.31 System data sets

Each installation must incorporate required system data sets into the system by allocating space for them on appropriate direct access devices during system installation. The DEFINE function of access method services is used to define both the storage requirements and the volume for each system data set. Some data sets must be allocated on the system residence volume, while some can be placed on other direct access volumes.

Before you install z/OS, you must select and define the system data sets that you need.

Before you include components from the distribution libraries (DLIBs) and user-defined data sets in the system, use JCL and access method services to define the system data sets. Figure 1-31 lists some of the common system data sets.
1.32 System administration

System administration tasks

Once you have the system up and running, most of your time is spent maintaining the system and providing technical support to the users. The remainder of this chapter describes some of the administrative tasks performed by a system programmer, specifically:

- User administration
- DASD administration
  - Adding a new DASD volume
  - Implementing DFSMS
  - Handling DASD problems
- System data housekeeping
  - SMF recording
    - SMFPRMxx parmlib member - Dumping SMF data
    - LOGREC data - SYSLOG data
- Other administration tasks
  - Working with MIH
  - Adding page data sets
  - Changing TSO timeout
  - Adding spool volumes
  - Deleting spool volumes
  - Verifying system configuration
  - Viewing SYSOUT using ISPF
  - Changing your TSO profile
  - Backing up and restoring z/OS
1.33 User administration

User administration
A system is never complete without users using it. Most of the time, you will find yourself having to perform certain user administration tasks. The next few sections provide examples of typical processes used when adding, deleting, or administering users.

Some of the common user administrative tasks are:

- Adding new users
- Creating RACF profiles for new users
- Modifying RACF profiles for existing users
- Resetting passwords
- Deleting users and their RACF profiles
1.34 DASD administration

On a large installation, you might have a team of storage administrators to take care of all DASD administration tasks, and you as a system programmer may only be required to help with obscure problems and exit routines. In that environment, you may never have to deal with the hardware side of DASD management, other than modifying IODF and IOCDS using HCD. On the other hand, your installation may be of a smaller scale that doesn’t warrant having a dedicated team of storage administrators, so you may have to take on far more of these roles.

DASD management
As a system programmer taking on the additional responsibility of a storage administrator, you might have to handle these aspects of DASD management:
- Adding new DASD devices and volumes to your system
- Implementing SMS
- Effectively managing catalogs
- Dealing with DASD problems
1.35 Adding a new DASD volume

**Figure 1-35   Adding a new DASD volume**

*Defined the new volumes through HCD and update IODF*

**How to add additional DASD volumes**

Figure 1-35 illustrates some DASD devices located inside the DASD controller. The following list outlines the steps for making a new DASD volume available to your system:

1. Physically connect the new device to the storage controller, which is connected to the system through an available channel. Normally, this task is performed by an IBM Customer Engineer who takes care of all the hardware installation.

2. Using HCD, update the IODF and IOCDS (a file in the processor controller) to include the new devices. You might want to define the device as belonging to one or more eligible device tables defined in your current IODF, so that data sets can be allocated on it using the UNIT parameter with the associated esoteric device name. For more information on how to use HCD, see *z/OS Hardware Configuration Definition User’s Guide*, SC33-7988.

3. Using the utility program ICKDSF, initialize each new volume with a volume serial label, a volume table of contents (VTOC), and a VTOC index. For more information on ICKDSF, see *Device Support Facilities User's Guide and Reference Release 17*, GC35-0033.

4. Vary the device online (candidate to receive data sets), and issue an appropriate MOUNT command, or re-IPL MVS to cause the new volume to be mounted according to the VATLST entries. Observe that this mount is just logical because the volume cannot be removed from the device.
A DASD volume that is not managed by DFSMS has mount attributes. Descriptions of the attributes are as follows:

**PRIVATE**  New data sets will be created on this volume only if the user (by using JCL or the TSO **ALLOCATE** command or an ISPF menu specification) specifies the volume serial number of this disk volume.

**PUBLIC**  MVS can place a temporary data set on this volume if the user (by using JCL or otherwise) did not specify a volume serial number for the temporary data set. Data sets may also be placed on this volume by specifying the volume serial number, as with the PRIVATE volumes. A temporary data set is one with a DSNAME beginning with an ampersand or with a disposition equivalent to NEW,DELETE. For more information about the DSNAME parameter in JCL, see z/OS MVS JCL Reference, SA22-7597.

**STORAGE**  MVS places permanent data sets on this volume if the user did not supply a volume serial number for the data sets. In addition, temporary data sets, and data sets placed by volume serial number, can also be placed on this volume.

You can set the volume use attributes by:

- Using the **MOUNT** operator command
- Using the VATLSTxx parmlib member

For more information on the **MOUNT** command, see z/OS MVS System Commands, SA22-7627.

**VATLSTxx parmlib member**

The VATLSTxx parmlib member defines the default mount and use attributes for disk volumes found during IPL. The mount attribute determines the conditions under which a volume can be unmounted, while the use attribute controls the type of request for which a volume can be allocated.

**Example of VATLSTxx:**

```
VATDEF IPLUSE(PRIVATE),SYSUSE(PRIVATE)
MPCAT1,1,0,3390,Y
MPRES1,1,2,3390,Y
MPRES2,1,2,3390,Y
```

This example specifies the use attribute. STORAGE is denoted by 0, PUBLIC by 1, and PRIVATE by 2.

For more information on the VATLSTxx parmlib member, see z/OS MVS Initialization and Tuning Reference, SA22-7592.
1.36 Implementing DFSMS

Implementing DFSMS

After you have added the new volumes to the system, you should not make all the volumes available to the users and allow them to use them as they wish. With no restriction on which volumes they can use or how much space they can allocate, your new disk volumes will be filled up fairly quickly. You could spend most of your time providing a new supply of disk volumes for other essential data, tracking down the owner of each data set to establish their importance, and trying to negotiate for space reduction. One way to solve this problem is to allocate individual volumes to each application, usage type, or group of users. Each of these volumes are mounted PRIVATE and allocation can be done by specifying the volume serial number. However, this method of control has some disadvantages:

- The requirement of specifying a volume serial number in JCL during allocation can lead to inflexibility; for example, a space allocation on one volume might fail even though there is a lot of space on other volumes available to the user.
- It is time-consuming and difficult to change the volumes available to the user because this requires changing the hard-coded volume serial number in the JCL.

To avoid these problems, you should implement data management techniques. Data management is the part of the operating system that automatically organizes, identifies, stores, catalogs, and retrieves all data information (including programs) that your installation uses. In the mainframe platform these functions are implement by a set of software products called DFSMS. Being more specific, DFSMS automates the management of DASD and tape storage, data security, data set placement, data set migration and recall, data set backup,
and data set recovery and deletion. This ensures that current data is available when needed and obsolete data is removed from storage, providing the following benefits:

- Simplified data allocation
- Ensured data integrity on new allocation
- Improved allocation control

The *ABCs of z/OS System Programming Volume 3*, SG24-6983 thoroughly covers the DFSMS details.
1.37 Handling DASD problems

How to deal with DASD problems

The most common hardware problem you will encounter in your role as a system programmer is a DASD I/O error.

The normal error handling processing by the storage subsystem (that is, the storage control and its attached storage devices) and by the operating system, z/OS, includes various functions that recognize errors and recover from them whenever possible. The storage subsystem performs the following functions:

- Adds ECC (error checking and correction) bits information to each field of a record when written. This ECC is checked when read from the disk. There is also ECC data with the communication with the channel.
- Detects errors in reading data, in performing control operations, in functioning of the hardware, and in programming. As an example, a disk error does not imply losing data due to the redundancy of RAID implementation.
- Retries I/O operations for certain error conditions.
- Assembles usage and error information in the form of sense information.
- Maintains counts of disk storage errors.
z/OS provides standard error recovery procedures to handle errors detected by the storage subsystem. For example, it:

- **Implements recovery actions** - The specific recovery actions depend on the particular error condition that was defined in the sense information sent from the storage subsystem; for example, retrying an operation when an equipment check is reported in the sense information.

- **Logs usage and error information records** - z/OS processes the sense information to produce and supplement data records describing the conditions under which the error occurred. The data describing the error is stored in the Error Recording Data Set (ERDS), that is SYS1.LOGREC. The EREP utility program formats error reports and may also perform error analysis based on information it obtains from the SYS1.LOGREC.

- **Issues system messages at the operator console** - System console messages may be the initial notification of I/O hardware or media problem. Most information messages contain data on the type and location of an error, and give sense information in hexadecimal format.

**EREP reports**

The errors shown on the EREP report should be followed up, particularly because temporary errors tend to lead to permanent errors. Normally, you will call an IBM Customer Engineer to look into the problem, or your hardware engineer if it turns out to be a hardware error. In the past, when we had real 3390 DASD, we had the possibility of doing track surface analysis. Now, this task is done by the DASD controller for its real disks without human interference.
1.38 System data housekeeping

To help you manage your system, z/OS generates various types of useful data and stores it in specific system data sets. There are four types of system data which you have to deal with:

- **System Measurement Facility (SMF) records** - The SMF records contain a variety of account information that enables you to produce many types of analysis reports and summary reports so that you can evaluate overall performance, changes in configuration, changes in workload, or job scheduling procedures by studying the trends in the data. You can also use SMF data to determine system resources wasted because of problems such as inefficient operational procedures or programming conventions.

- **LOGREC data** - The LOGREC data set contains statistical data about machine failures (processor failures, I/O device errors, channel errors). It also contains records for z/OS and subsystems program error, missing interrupt information, and dynamic device reconfiguration (DDR) actions.

- **SYSLOG data** - This data set resides in the JES spool data set. It records all the communications made by z/OS, application programs, and operators through MVS consoles, and it contains all console messages and operator commands for audit and diagnosis purposes. OPERLOG is a data set that merges all of the z/OS SYSLOGs in a Parallel Sysplex. It is very much recommended to implement OPERLOG to simplify tracking of an error within a sysplex.

- **System DUMP data sets** - These are sequential data sets containing system dumps that record areas of virtual storage in case of z/OS program task failures.
How to collect SMF data

SMF records are generated by hundreds of collecting routines spread all over the z/OS components and other software products. In general, SMF records describe the use of system resources by transactions. All the created SMF records are sent to I/O buffers in the SMF address space. When those buffers become full, a write I/O operation is executed, moving the records to z/OS VSAM data sets (SYS1.MANx). You have to allocate and catalog such data sets (at least two) on a high performance 3390 device because, if the rate of record creation is higher than the write I/O rate, you will lose SMF records.

IBM provides a utility program (IFASMFDP) that copies (dumps) the contents of a full SYS1.MANx data set to a tape or to a DASD data set. After such copy the SMF data set is flagged as empty and ready for a new load of SMF records.

Consider the following factors when determining which device type to specify when allocating SMF data sets:

- Your system configuration
- The amount of SMF data to be written
- The size of SMF buffers (the control interval size)
- Your installation’s report program requirement
The naming convention used for SMF data sets is SYS1.MANx, such as SYS1.MAN1, SYS1.MAN2, SYS1.MAN3, and so forth. You can use the following sample JCL to allocate new SMF data sets.

It is important to say that your installation must have software products (home made or purchased) able to receive SMF records and produce readable reports.

```verbatim
//DEFINE  JOB (), 'MVSSP', NOTIFY=&SYSUID, CLASS=A, MSGLEVEL=(1,1),
  MSGCLASS=X
//STEP1 EXEC PGM=IDCAMS
//SYSPRINT DD SYSOUT=* 
//SYSIN DD * 
DEFINE CLUSTER( 
  CONTROLINTERVALSIZE(4096) - 
  CYLINDERS(40) - 
  NAME(SYS1.MAN1) - 
  NONINDEXED - 
  RECORDSIZE(4086,32767) - 
  REUSE - 
  SHAREOPTIONS(2) - 
  SPANNED - 
  SPEED - 
  VOLUME(MTCAT1) ) - 
DATA( 
  NAME(SYS1.MAN1.DATA) ) 
/*
```
1.40 SMFPRMxx parmlib member

Once you have allocated all the required SMF data sets, you have to update the SMFPRMxx in SYS1.PARMLIB to reflect the new SMF data sets. In order to enable SMF recording, make sure that the first parameter in SMFPRMxx is set to ACTIVE, as shown in Figure 1-40.

To activate the new changes to SMF parameters, you can use the SET command to make them effective (assuming that you have added SYS1.MAN3 to SMFPRM00) as shown in the following example of issuing the SET command. (The notes referenced in this code are found on the following page.)
SMF found that SYS1.MAN3 has not been formatted. The formatting is now taking place.

The name of the SMF data set preceded by a P indicates that it is the primary SMF data set. If the name is preceded by an S, the data set is a secondary SMF data set.

**Types of SMF records**

You can control which SMF record types are recorded by using the SYS parameter in the SMFPRMxx parmlib member. You can specify SYS(TYPE(0:255)) to record all SMF records. However, this can create considerable overhead (by consuming lots of CPU and I/O resources) and fill up the SMF data sets very quickly. The default SYS parameter is SYS(NOTYPE(14:19,62:69,99)). This collects all SMF records except the following:

- Record type 14 is written for input non-VSAM direct access, tape data sets, or VIO data sets.
- Record type 15 is written for output non-VSAM direct access, or VIO data sets.
- Record type 16 is written to record information about events and operations of the sorting program.
- Record type 17 is written when a non-temporary data set or temporary data set is scratch.
- Record type 18 is written when a non-VSAM data set is renamed.
- Record type 19 is written for a list of online devices with specific IPL time frame.
- Record types 62 to 69 are written for various VSAM data sets and catalog activities.
- Record type 99 is written by the System Resource Manager (SRM) component when running in goal mode.

One of the most important SMF record types is the 30. It consolidates all the resource and time accounts consumed by an STC address space or batch job.

For more information about the rest of the SMF record types, see *z/OS MVS System Management Facilities (SMF)*, SA22-7630.
1.41 Dumping SMF data

When the current recording data set cannot accommodate any more records, the SMF writer routine automatically switches recording from the active SMF data set to an empty SMF data set and issues the following message regarding the full data set:

*IEE362A SMF ENTER DUMP FOR SYS1.MAN1 ON MPCAT1

You can use the sample JCL shown in the visual to dump the SMF data to a user data set and clear the SMF data set for reuse.

**OPTIONS(ALL)** indicates that the input data set specified in the DUMPIN DD statement is to be copied, then reset and pre-formatted.

**Note:** The output data set in the DUMPOUT DD statement should be large enough to hold one SMF data set; the minimum requirement is 30 cylinders.

The sample JCL Job can also be submitted through a console automation software product (such as AutoOperator) when the IEE362A message pops up.

Alternatively, you can code an IEFU29 exit to submit the job. The IEFU29 exit is invoked (if activated in SMFPRMxx) whenever an SMF data set switch occurs. For more information about the IEFU29 dump exit, see *z/OS MVS Installation Exits, SA22-7593.*
1.42 SMF recording to SYS1.MANx

**SMF recording**

SMF is a system component that captures system execution information and records it into the SYS1.MANx data set. Also, it has one interface that any application can invoke to report its performance flow and delays. This information is captured at a user-defined time interval and recorded in a data set for future processing. Some installations use the SMF information simply to manage their system and make performance adjustments in their system definitions. Other installations use the SMF information to bill their customers.

The amount of SMF record data increases over time. SMF writes these records in one VSAM data set called the SYS1.MANx data set, shown in Figure 1-42; when this fills up it switches to another one and marks the first one as dump required. When a subsystem or user program wishes to write an SMF record, it invokes the SMF record macro, SMFEWTM. This macro takes the user record and invokes SMF code to locate an appropriate buffer in the SMF address space and copies the data there. If the record is full, another SMF program is scheduled to locate full SMF buffers and write them to the SYS1.MANx data set. Each buffer is numbered to correspond to a particular record in the SMF data set. This allows the records to be written in any order and to be placed correctly in the data set. Although this is not shown in Figure 1-42, when all records have been written and the SYS1.MANx data set is full, SMF switches to a new SYS1.MANx data set, and marks the full one as DUMP REQUIRED. That data set cannot be used again until it is dumped and cleared. Scheduling the SMF dump program must be done in a timely manner to ensure that the SMF MANx data set is returned to use as soon as possible, thereby ensuring that no data is lost due to an “all data sets full” condition.
1.43 z/OS V1R9 SMF log stream recording

- Enhance SMF to record to System Logger log streams
  - Data buffered in multiple data spaces (1 per log stream), increasing buffering capacity
  - Data written to log streams by multiple tasks (1 per log stream), increasing write rate
  - Allow data to be partitioned to log streams as it is created
- Records can be recorded to multiple log streams
- Create new dump program to read log streams

The use of log streams for SMF Data is optional. Existing SYS1.MANx function continues to exist for installations satisfied with this functionality.

Figure 1-43  SMF recording options with z/OS V1R9

SMF recording using log streams
z/OS V1R9 introduces an additional optional capability to write SMF records to log streams managed by System Logger. With this new capability you can define several log streams for several groups of SMF records. You can define one log stream to write just the RMF records types, so during the post processor they are already isolated. When you define one log stream you have to define the SMF records type that will be written to this log stream. You can define a default log stream to write all the remaining SMF records types not defined to a specific log stream. This new support uses the following functions and improvements:

- Utilize System Logger to improve the write rate and increase the volume of data that can be recorded. System Logger utilizes modern technology, such as the Coupling Facility and media manager, to write more data at much higher rates than the current SMF SYS1.MANx data set allows.
- Provide better management of the data by enhancing SMF to record its data to multiple System Logger log streams based on record type. The record data is buffered in dataspaces, instead of the SMF address space private storage, thus allowing increased buffering capacity.
- Providing keywords on the OUTDD keyword of dump program that allows data to be read once and written many times. By recording different records to different log streams, SMF dump processing is also improved because one dump program per log stream can be submitted, with each being more efficient because fewer records are read and ignored. This reduces processing time because there is less filtering needed by the dump program.
1.44 SMF log stream recording

Recording to log streams

When recording to log streams, as shown in Figure 1-44, subsystems or user programs still invoke the SMFEWTM macro to take the user record and invoke SMF code. However, instead of locating a buffer in SMF private storage, SMF locates a dataspace corresponding to the user's record type and log stream where the record will be written. A buffer with space to hold the record is located and the record is copied there. When the record is full, a writer task is posted.

Unlike the scheduled approach in SMF data set recording, this task is already started and ready to write. In addition, writes to System Logger are done at memory-to-memory speeds, with System Logger accumulating many, many records to write out, resulting in an improved access currently not possible with SMF data set recording.

Using a dataspace to hold the records for a given log stream allows a full 2 GB of pageable memory to be used for buffering records in the event of delays in log stream writing in System Logger. This allows more data to be buffered than SMF data set recording, which is limited to the amount of available private storage in the SMF address space.

The benefit in all this is that you can write more data faster, with more functionality. The System Logger was created to handle large volumes of data. With minimal SMF switch processing and no record numbering schemes to maintain, this eliminates the switch SMF command bottleneck.
Coupling Facility or DASD-only log streams
There are two types of log streams, and SMF logging supports both of them:

- Coupling Facility log streams
  Data is stored in a Coupling Facility structure and then offloaded to DASD. A Coupling Facility log stream is ideal for merging SMF data from multiple systems. Make sure that a system’s SMF ID (SID) is unique within the sysplex.

- DASD-only log streams
  Data is stored in local storage buffers and then offloaded to DASD. DASD-only log streams can only be single-system in scope, and only one system can write data to any given DASD-only log stream.

Note: The use of log streams for SMF Data is optional. Existing SYS1.MANx function continues to be available for installations satisfied with this functionality.
1.45 SMFPRMxx parmlib member changes

- Choose SMF recording type - RECORDING keyword
  - SYS1.MANx or log stream
- Define log stream names - LSNAME keyword
  - Specify record types by log stream
- Activate parmlib via IPL or SET SMF=xx command
- SETSMF RECORDING can be used to change recording settings (for fallback)

```
RECORDING(DATASET | LOGSTREAM)
DEFAULTLSNAME(logstreamname)
LSNAME(logstreamname,TYPE{aa,bb}|{aa,bb:zz}))
```

| Figure 1-45 | Changes to the SMFPRMxx parmlib member |

**SMFPRMxx parmlib member**

Update the SMFPRMxx parmlib member to define the use of log streams and consider the following criteria:

- Plan to retain your SMF MANx data sets as a fallback plan.
- Update the procedures for SMF SWITCH processing and IEFU29 and IEFU29L exits.
- Update the procedures to indicate how the data will be archived when using log streams.

**Updating the SMFPRMxx parmlib member**

During initialization, SMF searches the SMFPRMxx parmlib member to see whether the system is using log streams or SMF data sets to record SMF data. To use the new SMF log stream facility you need to include some new statements in the SMFPRMxx parmlib member.

SMF MANx data sets can still be defined in the SMFPRMxx parmlib member if log streams are to be used. This allows for a fallback to SMF data sets if the exploitation of log streams encounters unexpected problems.

The new keywords are as follows:

```
RECORDING(DATASET | LOGSTREAM)
DEFAULTLSNAME(logstreamname)
LSNAME(logstreamname,TYPE{aa,bb}|{aa,bb:zz}))
```
1.46 Defining SMF system logging

- If you specify the same record type on two or more different LSNAME parameters
  - System writes the record to all specified log streams
- Could create a SMFPRMxx parmlib member with the following contents:

```
DEFAULTLSNAME (IFASMF.DEFAULT)
LSNAME (IFASMF.PERF,TYPE (30,89))
LSNAME (IFASMF.JOB,TYPE (30))
RECORDING (LOGSTREAM)
```

Choosing log stream names

The statement LSNAME specifies the log stream name that will be used for a particular group of SMF record types to be captured by this log stream. You can define a default log stream name on DEFAULTLSNAME, and request particular record types go to particular log streams using the TYPE subparameter on the LSNAME parameter. You can define several LSNAME statements to segregate the SMF records.

```
LSNAME (logstreamname,TYPE ([aa,bb]|[aa,bb:zz]))
```

- TYPE specifies the SMF record types that SMF is to collect to the specified log stream on the LSNAME parameter. aa, bb, and zz are the decimal notations for each SMF record type. You cannot specify subtypes on the TYPE subparameter for LSNAME. A colon (:) indicates the range of SMF record types (bb through zz) to be recorded.
- Value Range: 0-255 (SMF record types)
- Default: TYPE (0:255) (all types)

The log stream name must be composed as follows:

- The first seven characters must be IFASMF. If the first six characters are not IFASMF, the system issues an error message.
- You must have a minimum of 8 characters. A log stream name should be a unique descriptive identifier, made up of two or more qualifiers (each 1 to 8 characters in length) separated by periods (.), which you must count as characters. Each qualifier can contain up to eight numeric, alphabetic, or national ($, #, or @)
characters. The first character of each qualifier must be an alphabetic or national character.

- The maximum number of allowable characters is 26.
- It must conform to other log stream naming conventions as documented in IXGINVNT in z/OS MVS Programming: Assembler Services Reference, Volume 2 (IARR2V-XCTLX), SA22-7607.

**Note:** You can use system symbols and the &SID symbol in SMF log stream names. The resolved substitution text for the &SID system symbol is the system identifier specified on the SID parameter in SMFPRMxx.

Be aware that &SID can be used only to name resources in SMFPRMxx; you cannot specify &SID in other parmlib members.

### Choose SMF recording type

If the member specifies RECORDING(LOGSTREAM), SMF will write the SMF data to the log streams specified on the DEFAULTLSNAME and LSNAME parameters of the SMFPRMxx parmlib member. You can define DATASET or LOGSTREAM. The default is DATASET.

**RECORDING(DATASET | LOGSTREAM)**

Although you can identify both SMF data sets and log streams in the SMFPRMxx parmlib member, only one recording mechanism can be in use at a time. Use the following command to easily switch between recording types:

**SETSMF RECORDING(DATASET|LOGSTREAM)**

This facilitates both exploitation of the new function, as well as fallback in case of errors.

### Choose default log stream name

The optional statement DEFAULTLSNAME specifies the log stream name that will be used to capture the SMF records type not defined in any of the LSNAME statements. You should define another log stream name for the DEFAULTLSNAME following the same convention as for the of LSNAME statement.

**DEFAULTLSNAME(IFASMF.SSID.DEFAULT.SMF)**

### SMF record types to log streams

If you specify the same record type on two or more different LSNAME parameters, the system writes the record to all specified log streams. Figure 1-46 on page 73 shows one example of how to define the new statements in SMFPRMxx. In this case:

- Record type 30 will be written to both log streams IFASMF.PER and IFASMF.JOB.
- Record type 89 will be written to the IFASMF.PERF log stream.
- Record type 04 will be written to the IFASMF.JOB log stream.
- All the other SMF record types will be written to the IFASMF.DEFAULT log stream.
1.47 SMF dump program for log streams

- New JCL for the IFASMFDL dump program to dump new log streams
- Reduce processing time as less filtering needed by dump program
- Provide better management of the data by separating different record types into a number of different log streams
- Providing keywords on the OUTDD keyword of dump program that allow data to be “read once, written many”

Dumping the SMF log stream data set
With z/OS V1R9, a new SMF dump program called IFASMFDL is available. The IFASMFDP utility is used to process the SMF MANx data sets, isolate the records, create files to be post-processed, and clean the MAN data sets. Now, with log stream data sets, the new IFASMFDL utility reads the log streams and can create several different files as required in just one step.

The record data from the new SMF dump program IFASMFDL should be virtually indistinguishable from data dumped by the SMF data set dump program IFASMFDP. You will just need to change your JCL to use the new IFASMFDL utility.

IFASMFDL dump program utility
The SMF log stream dump program dumps the contents of one or more log streams to sequential data sets on either tape or direct access devices. The SMF log stream dump program allows the installation to route different records to separate files and produce a summary activity report.

A new feature in the SMF log stream dump program is the addition of filters on the OUTDD statements. Previously, each OUTDD would receive all the records specified on the main filter keywords of DATE/START/END/SID. If it was required to create different OUTDD data sets with different records from the same input, it was necessary to run the dump program a second time to create that second data set.
Now, with the new IFASMFDL utility, it is possible to specify those same filters on the OUTDD statement, allowing the capability to read the log stream one time, and partition the output, sending different records to different data sets. This should result in fewer invocations of the dump program being required, in turn causing less impact to the system by reading the log stream only once.

**Note:** A feature in the SMF dump program for log streams allows you to partition output data based on date, time, and SMF ID (SID).
1.48 Sample JCL to dump SMF log streams

```
//IFASMFDDL JOB accounting information
//STEP EXEC PGM=IFASMFDDL
//OUTDD1 DD DSN=SMFREC.FEWTYPES,DISP=(NEW,CATLG,DELETE)
//OUTDD2 DD DSN=SMF.TYPE10.TYPE255,DISP=(NEW,CATLG,DELETE),
//    DCB=BLKSIZE=32000
//OUTDD3 DD DSN=SMF.TYPE10.TYPE255B,DISP=(NEW,CATLG,DELETE),
//    DCB=LRECL=32760
//SYSPRINT DD SYSOUT=A
//SYSSIN DD *

LSNAME (IFASMF.DEFAULT)
LSNAME (IFASMF.PERF)
LSNAME (IFASMF.JOB)
OUTDD (OUTDD1,TYPEx(0,2,10,15:30,33(1)),START(0730),END(1850))
OUTDD (OUTDD2,TYPEx(10:255)),DATE(2006274,2006334)
OUTDD (OUTDD3,TYPEx(10:255))
DATE (2006001,2006365)
SID (308A)
SID (308B)
END (2400) - DEFAULT
START (0000) - DEFAULT
```

*Figure 1-48  JCL to dump SMF log streams*

**IFASMFDDL utility example**

In the example shown in Figure 1-48, the three OUTDD statements refer to the three data sets defined in the JCL, and they specify the SMF record types to be written to each data set. The JCL is explained as follows:

- The **DCB=** keyword has been coded for the output data set defined by OUTDD2. Any block size 4096 or greater can be specified. Choosing a block size suitable for the device type being used will improve storage resource use. For this job, the data set specified by OUTDD1 will have a system-determined block size. The data set specified by OUTDD2 will have a block size of 32000.
- The **LRECL=** keyword has been coded for an output data set defined as OUTDD3. For this job, the data set specified by OUTDD3 will have an LRECL of 32760. For OUTDD1 and OUTDD2, the LRECL will default to 32767.
- The **LSNAME** parameters contain the names of three log streams to be dumped.
- The **OUTDD** parameters contain filters selecting the SMF record types to be dumped:
  - OUTDD1 specifies that you want to dump record types 0, 2, 10,15-30, and subtype 1 of record type 33, starting with those issued at 7:30 am and ending at 6:50 pm.
  - OUTDD2 specifies that you want to dump record types 10 through 255 from dates October 1, 2006 through November 30, 2006.
  - OUTDD3 specifies that you want to dump record types 10 through 255.
The DATE parameter specifies, for those OUTDD statements which do not include the DATE subparameter, that data from January 1, 2006 through December 31, 2006 is to be written.

The SID parameters specify that data will be dumped for systems 308A and 308B.

**Note:** There can be any number of input (LSNAME) or output (OUTDD) parameters in the SMF log stream dump program. The log streams are dumped in reverse order.

For example, in Figure 1-48 on page 77, three log streams are specified. After the SMF log stream dump program is processed, the output files contain the records from log stream IFASMF.JOB first, IFASMF.PERF next, followed by the records from IFASMF.DEFAULT.

**IFASMFDL utility output**

If you want to use the SMF log stream facility to take advantage of the high speed services that IXGLOGR can provide, and you also want to keep your old way of storing your SMF data, then you can do it using this new utility. You can define your retention period as long as you need to copy them.

**Note:** SMF recording to the MANx data sets is retained in this release and the current configuration can remain as it is. In this release, the record data from the new SMF dump program IFASMFDL should be virtually indistinguishable from data dumped by the SMF data set dump program IFASMFDP.

There are expected changes to vendor code that uses “live” SMF data, that is, data that is still resident in the SMF “MAN” data sets. Vendor programs that read data from data sets created by the SMF dump program, as indicated above, are not affected.
1.49 LOGREC data

How to create SYS1.LOGREC

When a system error occurs, z/OS records information about the error in the LOGREC data set. The information provides you with a history of all hardware failures, selected z/OS and subsystem software errors, and selected system conditions. Observe that software application abends and errors are not reported in SYS1.LOGREC. You can use the Environment Record, Editing, and Printing (EREP) program to:

- Print reports about the system records
- Determine the history of the system
- Learn about a particular error

Before the system can record all this information, you must first allocate the logrec data set and initialize it.

**Note:** Whenever you allocate or reallocate the logrec data set, the newly allocated data set will not be used until you initialize it and IPL the system on which it is to be used.

You can use the following sample JCL to create and initialize a new logrec data set:
The SYS1.LOGREC has a z/OS scope, meaning that there is one per each z/OS in the sysplex. If you use the default name SYS1.LOGREC in a sysplex environment, take care to ensure that the logrec data set is uniquely specified with the volume-serial. This prevents the initialization of another system’s logrec data set in the event that IFCDIP00 is run on a different system.

**How to clear SYS1.LOGREC**

The logrec data set will eventually become full, just like the SMF data set, and console messages appear requesting the operator to take action. Therefore, this data set needs to be cleared so that it can be reused. The process is a little different because there is only one logrec data set.

As a system programmer, you have to set up an automatic process to clear the logrec data set when the following message appears:

```
IFB080E LOGREC DATA SET NEW FULL, DSN=SYS1.LOGREC
```

This is issued when the logrec data set becomes 90 percent full; if action is not taken and logrec fills up completely, the following message, which requires prompt action, is issued:

```
IFB081I LOGREC DATA SET IS FULL, hh.mm.ss, DSN=SYS1.LOGREC
```

At this stage, if you do not take any action, the system continues processing, but further error records will be lost. You can use the following sample JCL to clear the logrec data set:

```
//LOGREC JOB (),'MVSSP',NOTIFY=&SYSUID,CLASS=A,MSGLEVEL=(1,1),
// MSGCLASS=X

//**********************************************
//* CREATE A NEW LOGREC DATASET AND INITIALIZE IT
//**********************************************
//STEP1 EXEC PGM=IFCDIP00,COND=(4000,LT)
//SERERDS DD UNIT=SYSDA,VOL=SER=MPRES1,SPACE=(CYL,3,,CONTIG),
// DSN=SYS1.LOGREC,DISP=('CATLG

//CLRLOG JOB (),'MVSSP',NOTIFY=&SYSUID,CLASS=A,MSGLEVEL=(1,1),
// MSGCLASS=X

//STEP EXEC PGM=IFCEREP1,PARM='CARD'
//SERLOG DD DSN=SYS1.LOGREC,DISP=OLD
//ACCDDEV DD DSN=SYS1.LOGREC.TEMPSTOR,DISP=MOD
//TOURIST DD SYSOUT=*
//EREPT DD SYSOUT=*
//SYSIN DD DUMMY

//SYSUM ACC=Y
//ZERO=Y
```

The job will copy the logrec data set to the data set specified in the DDNAME ACCDEV, print a brief summary of logrec data, and then clear the data set. For more information about the rest of the parameters, see *Environmental Record Editing and Printing Program (EREP) Reference*, GC35-0152.
1.50 SYSLOG data

SYSLOG data set

An MVS console is a terminal device where human operators exchange information (data) with software. This data is called messages when coming from the software and replies or commands when coming from the operator (or automation software). The software exchanging such data can be: z/OS components, subsystem products such as DB2 and CICS, and application programs. The communication task is the z/OS component in charge of the console I/O. Two communication task functions can be used by software to send messages to the console: WTO and WTOR. For performance and availability reasons it is recommended to have several consoles in a z/OS environment.

In some installations the operator could be partially replaced by automation software, which emulates human operators.

All the messages, replies, and commands in all the z/OS consoles are stored in a log file, either OPERLOG or SYSLOG. This file is part of the SYSLOG data set that is stored in a JES (JES2 or JES3) spool data set as a SYSOUT data set. There are two major uses for the SYSLOG: problem determination and audit.

In addition to the hardcopy log, the SYSLOG consists of the following:
- All messages issued through Write To Log (WTL) macros
- All messages entered by the LOG operator commands
- Any messages routed to the SYSLOG from any system component or program

Figure 1-50  SYSLOG data
The SYSLOG is a SYSOUT data set provided by the job entry subsystem (either JES2 or JES3).

**Note:** With JES3, the SYSLOG is a combined log of messages of all systems in the sysplex.

SYSOUT data sets are 132 characters per line, stored on direct access storage devices (DASD). An installation should print the SYSLOG periodically to check for problems. You can limit the maximum number of messages allowed for the SYSLOG at IPL time by using the LOGLMT parameter in the IEASYSxx parmlib member. The value is used by log processing to determine when the SYSLOG should be scheduled for sysout printing processing by JES. When this value is reached, the log processing:

- Issues a simulated WRITELOG command to close and free the current SYSLOG.
- Releases the closed SYSLOG to the printer queue whose output class is specified by the LOGCLS parameter of the IEASYSxx parmlib member.
- Allocates and opens a new SYSLOG.

Example of LOGLMT and LOGCLS in IEASYSxx:

```plaintext
LOGCLS=L, LOGLMT=99999
```

In this example, the SYSLOG is scheduled for SYSOUT processing on output class L when 99,999 messages have been stored in SYSLOG. For more information on LOGLMT and LOGCLS, see z/OS MVS Initialization and Tuning Reference, SA22-7592.

Remember that the SYSLOG provides a permanent, consolidated record of all console messages and commands, that is, the event log of the system. Thus, you might want to review the SYSLOG at a later date when you are doing problem diagnosis. Instead of having the SYSLOG written to the output queue after a certain number of WTLs, you should set up a procedure to organize the SYSLOG data set depending on your installation's requirement.

You can perform your housekeeping as follows:

1. Set up a procedure to have the system operator issue the WRITELOG command to close and allocate a new SYSLOG at the end of each processing day. For example, WRITELOG H.

   **Note:** Class H is not a default printer class, so the SYSLOG data set is kept in the spool.

2. At the end of the week, you will have seven SYSLOG data sets in the spool. You can now decide to offload the SYSLOG to an MVS data set or route it to a printer for a hardcopy printout.

3. It's really not necessary to keep SYSLOG data sets for more than a week, so if you keep a week's worth of SYSLOG data sets, you should not have a problem.

If you have a Parallel Sysplex, it is recommended to merge all the z/OS SYSLOGs in an OPERLOG data set. This OPERLOG is sorted by time stamp for all the commands, replies, and messages issued in the Parallel Sysplex. With OPERLOG you can speed up the problem determination processing in a Parallel Sysplex complex.
1.51 Other administration tasks

In the remainder of this chapter we discuss some other administrative tasks and techniques. Specifically, we show you how to:

- Work with missing interrupt handler (MIH) and hot I/O components
- Add page data sets
- Change TSO timeout
- Add JES spool volumes
- Delete JES spool volumes
- Verify Hardware Configuration Definition (HCD) configuration
- View SYSOUT in JES2 spool using ISPF
- Change your TSO profile
- Back up and restore z/OS data sets
1.52 Working with MIH and hot I/O

How to work with missing interrupt handler (MIH)

When z/OS sends channel commands to a control unit, through an asynchronous I/O operation (started with the SSCH instruction), it expects a response about the end of such I/O operation (maybe the requesting task is in wait state). This response is materialized through an I/O interrupt. If no I/O interrupt is received from the channel after a certain amount of time, a missing interrupt situation exists. This is an error situation and the MIH component is invoked. The following conditions qualify as missing interrupts if the specified time interval has elapsed:

- Primary status interrupt pending, also called channel end
- Secondary status interrupt pending, also called device end
- Start pending condition, the I/O request is still queued in IOS component because the device is still busy
- Idle with work queued, the I/O request is still queued in IOS component and the device is not busy
- Mount pending

You can use the IECIOSxx parmlib member to specify the timing limits for device types in your system. For any detected missing interrupt, the MIH performs one or more of the following actions:

- Invoke the device dependent MIH exit (if it exists).
Record the condition in the SYS1.LOGREC data set.
Notify the system operator through an MVS console message.
Clear the condition.
Simulate an interrupt informing an errors situation to the requesting waiting task.
Redrive the device, executing the I/O again.
Requeue the I/O request.
Swap the primary device for a secondary device that is mirroring the primary in another DASD controller (HyperSwap™).

When specifying time intervals, consider the following:
- MIH detects a missing interrupt condition within 1 second of the time interval that you specify.
- If the time interval is too short, a false missing interrupt can occur and cause early termination of the channel program. For example, if a 30-second interval is specified for a tape drive, a rewind might not complete before the MIH detects a missing interrupt.
- If the time interval is too long, a job or system could hang because the MIH has not yet detected a missing interrupt. For example, if a 15-minute time interval is specified for a tape drive used as an IMS log tape, the MIH could delay IMS for 15 minutes because of MIH detection.

Hot I/O refers to an I/O hardware malfunction that causes repeated, unsolicited I/O interrupts, exactly the opposite of MIH. If those I/O interrupts are not disabled, the z/OS can loop or the System Queue Area (SQA) can be depleted, forcing an unplanned IPL. The IOS component tries to detect the hot I/O condition and performs recovery actions before the system requires an IPL. Recovery actions taken for a hot device depend on the type of device and its reserve status. You can use the HOTIO statement in IECIOSxx, as shown in the following example, to modify the Hot I/O Detection Table (HIDT), and to eliminate operator intervention where recovery actions defined in HIDT (by default) require the operator to respond to a message.

```
HOTIO DVTHRSH=200
MIH TIME=00:30,DEV=(2E8-2FF,7300-7370)
HOTIO DFLT111=(CHPK,CHPF),DFLT112=(CHPK,OPER)
MIH IOTIMING=00:12,DEV=(2E8-2FF,730-737)
MIH TIME=00:00,DEV=(180-187,230,B10-B17)
```

Once you have updated the IECIOSxx parmlib member, you can activate the changes using the SET command, as shown in the following example:

```
SET IOS=00
IEE252I MEMBER IECIOS00 FOUND IN SYS1.PARMLIB

IEE536I IOS VALUE 00 NOW IN EFFECT
```

For more information on the IECIOSxx parmlib member, see z/OS MVS Initialization and Tuning Reference, SA22-7592.
1.53 Adding a page data set

How to add additional page data sets

z/OS can support a large amount of virtual storage by using paging data sets to handle the amount of pages overflowing from central storage. VSAM ESDS named page data sets are used to contain those pages. Another term often used to collectively describe these page data sets is auxiliary storage, which is managed by the auxiliary storage manager (ASM).

As your workload increases, you may run out of available auxiliary storage. When the system detects a shortage of available slots in the auxiliary storage paging space, meaning that 70 percent of available slots are already in use, it issues the following message:

IRA200E AUXILIARY STORAGE SHORTAGE

The system rejects LOGON, MOUNT, and START commands until the shortage is relieved.

If no action is taken, the system issues the following message when 90 percent of all available auxiliary storage is in use:

IRA201E CRITICAL AUXILIARY STORAGE SHORTAGE

Adding page data sets

There are two solutions to this problem:

- Increase dynamically the auxiliary storage available for z/OS use by defining dynamically more page data sets.
Cancel the address space that is producing the most of pages (through the getmain function).

You can use the sample JCL that follows to define a new page data set.

```
//DEFPAGE JOB (),'MVSSP',NOTIFY=&SYSUID,CLASS=A,MSGLEVEL=(1,1),
 // MSGCLASS=X
//STEP1 EXEC PGM=IDCAMS,COND=(4000,LT)
//SYSPRINT DD SYSOUT=* 
//PAGELOC DD UNIT=3390,VOL=SER=MPCAT1,DISP=OLD
//SYSIN DD *
  DEFINE PAGESPACE( -
    FILE(PAGELOC) -
    NAME(PAGE.SC65.LOCAL3) -
    CYLINDERS(200) -
    VOLUME(MPCAT1) )

PAGEADD PAGE=PAGE.SC65.LOCAL3
  IEE783I PAGEADD COMMAND- 531
  PAGE.SC65.LOCAL3 PAGE DATA SET
  NOW AVAILABLE FOR SYSTEM USE

PAGEDEL COMMAND IS NOT ACTIVE
```

After you have successfully defined a new page data set, you can relieve the auxiliary shortage by adding the new page data set to the system as shown in the following example.

```
PAGE=(PAGE.SC65.PLPA, PAGE.SC65.COMMON, PAGE.SC65.LOCAL1, PAGE.SC65.LOCAL2, PAGE.SC65.LOCAL3),L)
```
1.54 Changing TSO timeout

How to change the TSO timeout value

After a period of inactivity, TSO automatically logs a user off. This elapsed time is set in the SMFPRMxx parmlib member using the parameter JWT(hhmm), as shown in the following example where *hh* is the amount of real time in hours and *mm* is in minutes.

```plaintext
ACTIVE                        /*ACTIVE SMF RECORDING*/
DSNAME(SYS1.MAN1, SYS1.MAN2, SYS1.MAN3) /*SMF DATA SET NAMES*/
NOPROMPT                       /*NO PROMPTING*/
JWT(0030)                      /*522 AFTER 30 MINS*/
```

Figure 1-54 Changing the TSO timeout value

```plaintext
SMFPRMxx
ACTIVE                        /*ACTIVE SMF RECORDING*/
DSNAME(SYS1.MAN1, SYS1.MAN2, SYS1.MAN3) /*SMF DATA SET NAMES*/
NOPROMPT                       /*NO PROMPTING*/
JWT(0030)                      /*522 AFTER 30 MINS*/
```

SMFPRMxx

```plaintext
ACTIVE                        /*ACTIVE SMF RECORDING*/
DSNAME(SYS1.MAN1, SYS1.MAN2, SYS1.MAN3) /*SMF DATA SET NAMES*/
NOPROMPT                       /*NO PROMPTING*/
JWT(0030)                      /*522 AFTER 30 MINS*/
```

TSO logon proc

```plaintext
000100 //TSPROC PROC
000200 //*------This is a comment line -----------------------
000300 //TSPROC EXEC PGM=IKJEFT01,DYNAMNBR,TIME=1440
```

```plaintext
000100 //TSPROC PROC
000200 //*------This is a comment line -----------------------
000300 //TSPROC EXEC PGM=IKJEFT01,DYNAMNBR,TIME=1440
```

How to change the TSO timeout value

After a period of inactivity, TSO automatically logs a user off. This elapsed time is set in the SMFPRMxx parmlib member using the parameter JWT(hhmm), as shown in the following example where *hh* is the amount of real time in hours and *mm* is in minutes.

```plaintext
ACTIVE                        /*ACTIVE SMF RECORDING*/
DSNAME(SYS1.MAN1, SYS1.MAN2, SYS1.MAN3) /*SMF DATA SET NAMES*/
NOPROMPT                       /*NO PROMPTING*/
JWT(0030)                      /*522 AFTER 30 MINS*/
```

Figure 1-54 Changing the TSO timeout value

```plaintext
ACTIVE                        /*ACTIVE SMF RECORDING*/
DSNAME(SYS1.MAN1, SYS1.MAN2, SYS1.MAN3) /*SMF DATA SET NAMES*/
NOPROMPT                       /*NO PROMPTING*/
JWT(0030)                      /*522 AFTER 30 MINS*/
```
In the example, a user is forced off after 30 minutes of no activity. You can edit this PARMLIB member and change this value. You can set this new value by using the `SET` operator command:

```
SET SMF=00
```

**Note:** There is a possibility that TSO users are not being timed out when the value specified in the JWT parameter has expired. This usually happens when `TIME=1440` is specified in the TSO logon procedure that the users used to log on to the system.

```
//TSPROC PROC
//TSPROC EXEC PGM=IKJEFT01,DYNAMNBR=256,TIME=1440
```

The `TIME=1440` is a special value that will:

- Allow the particular job to run for an unlimited amount of time
- Ignore the JWT parameter in SMFPRMxx parmlib member for the job

The logon procedure is JCL describing the resources (data sets, virtual storage, programs) that are allocated to your TSO address space when you log on.
1.55 Adding spool volumes in JES2

How to add spool volumes

The JES2 spool is the repository for all input jobs and system out (SYSOUT) that JES2 manages. Due to fluctuating workload requirements, such as I/O errors, hardware failures, or utilization needs, you might need to add spool space by adding another volume.

Spool volumes are added either at cold start or dynamically through the use of the JES2 operator command $S SPL. You can define a maximum of 253 spool volumes to JES2 at any one time.

To define the spool volumes during JES2 startup, use the SPOOLDEF statement in the JES2 PARM. The SPOOLDEF statement that follows is an example in the JES2 PARM. (Notes referenced in the code are on the following page.)

```
SPOOLDEF BUFSIZE=3856, /* MAXIMUM BUFFER SIZE &BUFSIZE c*/
    DSNNAME=SYS1.MHQPROD.HASPACE,
    FENCE=NO,           /* Don't Force to Min.Vol. &FENCE oc*/
    SPOOLNUM=32,        /* Max. Num. Spool Vols c*/
    TGBPERVL=5,         /* Track Groups per volume in BLOB ownc*/
    TGSIZE=33,          /* 30 BUFFERS/TRACK GROUP &TGSIZE wnc*/
    TGSPACE=(MAX=16288, /* Fits TGMs into 4K Page &NUMTG=, c*/
        WARN=80),  /*                       &NUMTG=(,% onc*/
    TRKCELL=3,          /* 3 Buffers/Track-cell &TCELSIZ c*/
    VOLUME=MPSPL        /* SPOOL VOLUME SERIAL &POOL c*/
```
1. The JES2 spool data set name.

2. This specifies the maximum number of spool volumes which can be defined at any one time.

3. Specifies the four- to five-character prefix assigned to JES2's spool volumes. The first four to five characters of the volume serial must be identical to the character specified by this parameter. Those volumes beginning with this prefix and a data set named the same as the DSNAME specification are considered JES2 volumes.

Note: If the maximum of 253 spool volumes is exceeded during a cold start, JES2 issues a message informing the operator that more spool volumes were found than expected from the SPOOLNUM parameter on the SPOOLDEF initialization statement.

As mentioned, you can also add spool volumes dynamically by using operator command, $S SPL as shown in the following example:

```
$S SPL(MPCAT2)
$HASP893 VOLUME(MPCAT2)  STATUS=INACTIVE,COMMAND=(START)
$HASP646 16.9066 PERCENT SPOOL UTILIZATION
IEF196I IEF237I 0805 ALLOCATED TO $MPCAT2
IEF196I $HASP423 MPCAT2 IS BEING FORMATTED
$HASP423 MPCAT2 IS BEING FORMATTED
$HASP850 3750 TRACK GROUPS ON MPCAT1
$HASP850 586 TRACK GROUPS ON MPCAT2
$HASP851 28232 TOTAL TRACK GROUPS MAY BE ADDED
$HASP630 VOLUME MPCAT2 ACTIVE     0 PERCENT UTILIZATION
```

Note: If the dynamic addition of another spool volume is attempted (thereby exceeding the maximum of 253 spool volumes), the command will be ignored, the volume will not be added, and the message $HASP411 will be issued to the operator.
1.56 Deletion of spool volumes in JES2

**How to delete spool volumes**

Spool volumes can be deleted dynamically as needed to meet your installation's requirements, using the operator commands:

- **$Z SPL**
- **$P SPL**

Some considerations must be recognized and precautions must be taken to prevent improper usage of the spool volume deletion commands, specifically:

- If the volume being deleted (halted or drained) contains spooled or remote messages or the JESNEWS data set, these items are automatically moved to another volume.

**Note:** This process may take some time because spooled remote messages and SYSOUT are only moved from the draining volume when they become the lowest-numbered job on the volume.

- If there are no active volumes available for these data sets, the deletion process will not complete until an active volume is available to accept them.

You use the **$Z SPL** command to halt an active spool volume. When you issue the **$Z** command, no new work is allowed to start and no new space on the volume is allocated. Any currently allocated space remains intact and the volume can be removed without the loss of work.
The volume status is HALTING until all currently active jobs which have space allocated on the volume are completed. After that the status of the volume changes to INACTIVE. System response to the $Z command is shown in the following example:

```
$ZSPL,V=MPCAT2
$HASP893 VOLUME(MPCAT2) STATUS=ACTIVE,COMMAND=(HALT)
$DSPL
$HASP893 VOLUME(MPCAT1) STATUS=ACTIVE,PERCENT=13
$HASP893 VOLUME(MPCAT2) STATUS=HALTING,PERCENT=16
$HASP646 13.7066 PERCENT SPOOL UTILIZATION

$HASP395 LSTDDF ENDED
$HASP309 INIT B INACTIVE ******** C=GA
IEF1961 IEF285I SYS1.MHQPROD.HASPACE KEPT
IEF1961 IEF285I VOL SER NOS= MPCAT2.
$HASP630 VOLUME MPCAT2 INACTIVE 16 PERCENT UTILIZATION
```

1. The initial status of the spool volume, MPCAT2 was ACTIVE.
2. To display the status of spool volumes, you used the $DSPL command.
3. After the $Z command was issued, the status changed to HALTING.
4. When the job (LSTDDF) ends, the status of the spool volume (MPCAT2) changed to INACTIVE.

To drain and delete an entire spool volume, you can use the $P SPL operator command. The command prevents any available tracks on the draining spool volume from being selected for allocation. Until all jobs currently allocated to the volume have completed all phases of job processing, the volume is considered to have a status of draining. The spool volume is drained when no allocated spool space remains on that volume, and the volume is unallocated to all systems in the multi-access spool complex.

**Note:** Once the spool volume is drained, JES2 does not retain any information concerning that volume. Therefore, you cannot display any information about the volume.

The following example shows the system response when you issue the $P SPL command when an active job is running:

```
$PSPL(MPCAT2)
$HASP893 VOLUME(MPCAT2) STATUS=ACTIVE,COMMAND=(DRAIN)
$HASP646 1.9142 PERCENT SPOOL UTILIZATION
$DSPL
$HASP893 VOLUME(MPCAT1) STATUS=ACTIVE,PERCENT=1
$HASP893 VOLUME(MPCAT2) STATUS=DRAINING,PERCENT=1
$HASP646 1.9200 PERCENT SPOOL UTILIZATION
```

1. The initial status of the spool volume to be drained.
2. After the $PSPL(MPCAT2) command was issued, the status of the spool volume (MPCAT2) changed to DRAINING.

If you want to cancel and deallocate all cancellable jobs on the drained spool volume, you can use the CANCEL operand together with the $P SPL command. All jobs and SYSOUT will be
deleted from the volume; any spooled remote messages and the JESNEWS data set (if present) are automatically moved to another active spool volume.

**Note:** The `$S\, SPL,\, CANCEL` command can also be used to drain an inactive volume, purging all jobs allocated to it. However, this can result in lost track groups on other volumes. You can recover any lost space by doing an all-member warm start, or the JES2 automatic spool reclamation function will also recover them within one week, whichever occurs first. You can prevent the loss of spool space by using the `$S\, SPL,\, P,\, CANCEL` command only if the spool volume can be remounted.

An example of the `$S\, SPL,\, P,\, CANCEL` command is shown, as follows:

```
$SSPL(MPCAT2),P,CANCEL 1
$HASP893 VOLUME(MPCAT2) STATUS=DRAINING,COMMAND=(START,DRAIN)
$HASP646 7.1200 PERCENT SPOOL UTILIZATION
  .
  .
  .
IEF196I IEF285I SYS1.MHQPROD.HASPACE KEPT
IEF196I IEF285I VOL SER NOS= MPCAT2.
$HASP806 VOLUME MPCAT2 DRAINED 2
```

1 The command will fail with the message: REQUEST INVALID DUE TO ACTIVE STATUS if the spool volume is not in the DRAINING status.

2 At the successful completion of the command the status of the spool changed to DRAINED, which indicates you can no longer display any information about the volume.

**Note:** If all the spool volumes are deleted, JES2 will not be capable of performing any work. Hence, be very careful when you delete any spool volumes.

For more information on the use and syntax of the spool configuration commands, see *z/OS JES2 Commands*, SA22-7526.
1.57 Verifying the system configuration

How to verify the system configuration

Hardware Configuration Definition (HCD) is a z/OS component running under TSO/ISPF through which, using panels, you describe your hardware configuration. The following items can be defined: processors, Logical Channel Subsystems, logical partitions, channels, switches (directors), controllers, and devices.

When you start an HCD session, you need to specify the IODF data set that HCD uses to keep the configuration. Before you can activate your configuration, you must build a production IODF, usually based on a previous IODF. The IODF data sets must be cataloged.

The CONFIGxx parmlib member is a list of records that an installation can use to define a standard configuration of system elements. Usually, this is created by HCD (through the Build CONFIGxx HCD member option). You can use the configuration defined in CONFIGxx in two ways:

- To compare the differences between the current configuration and the standard configuration as defined in a CONFIGxx member. To do that, use the DISPLAY M=CONFIG(xx) operator command.
- To reconfigure some of the system elements by using the CONFIG operator command with the MEMBER option.

The CONFIGxx parmlib member can also be created manually, as described in the z/OS MVS Initialization and Tuning Reference, SA22-7592.
1.58 Creating CONFIGxx member in batch

You can also use a batch job to create the CONFIGxx member. The JCL in Figure 1-58 is a sample to accomplish the task. The following notes apply to this code:

1. This parameter creates a CONFIG00 member with the Processor ID (SCZP601), Partition ID (A1) and OS configuration ID (L06RMVS1).
2. This specifies the Source IODF.
3. This specifies the output partitioned data set for CONFIGxx.

For more information, see z/OS Hardware Configuration Definition User's Guide, SC33-7988.

When you issue the DISPLAY M=CONFIG(xx) operator command, the system displays the differences between the current configuration and the configuration described in the CONFIGxx parmlib member. The default suffix of the CONFIGxx is 00.

If the existing configuration matches the one specified in the CONFIGxx, the following message is shown:
On the other hand, if there is any mismatch between the existing configuration and that defined in the CONFIGxx, the following message is shown. (Note that this is only an example; you might receive something different depending on the specific deviation from the configuration.)

```
D M=CONFIG
IEF196I IEF237I OFCO ALLOCATED TO SYS00118
IEE252I MEMBER CONFIG00 FOUND IN SYS1.PARMLIB
IEE097I 11.07.34 DEVIATION STATUS 633
   FROM MEMBER CONFIG00
   NO DEVIATION FROM REQUESTED CONFIGURATION

CHP          DESIRED  ACTUAL
20           ONLINE   NOT AVAILABLE
DEVICE      DESIRED  ACTUAL
0790,95      ONLINE   OFFLINE
```
Subsystems and subsystem interface (SSI)

This chapter describes basic concepts that you need to understand if you want to write your own subsystem or want to use services provided by IBM subsystems. In a sense, a subsystem is a very clever software Application Program Interface (API) that is described in this chapter.

When you want to write your own subsystem, you must:

- Provide the routines to support the request for a function. These function routines get control from the SSI. They may actually perform the function or may pass control to other routines that you provide.
- Provide a subsystem address space (if required).
- Let MVS know that the subsystem exists (define the subsystem).
- Provide the information to the SSI that it needs to find your function initial routines (initialize the subsystem).
- Provide accounting information parameters to your subsystem (if required).

**Note:** When writing your own subsystem you must also provide any control blocks or resources that the subsystem requires for its own operation, which z/OS does not provide.
2.1 Defining subsystems and subsystem interface

- **What is a subsystem?**
- **Types of subsystems**
  - Master
  - Job entry or primary
  - Secondary
  - Functional
- **What is the SSI**
- **Unique attributes of the SSI**

![Figure 2-1  Defining subsystems and subsystem interface](image)

**Defining subsystems**

A subsystem is a software service provider that performs one function or many functions, but does nothing until it is requested. Although the term “subsystem” is used in other ways, a subsystem must be the master subsystem or be defined to z/OS in one of the following ways:

- Processing the IEFSSNxx parmlib member during IPL
  
  Each entry defines one subsystem through its name. You can use either the keyword format or positional format of the IEFSSNxx parmlib member. We recommend that you use the keyword format, which allows you to define and dynamically manage your subsystems.

- Issuing the IEFSSI macro in a program
- Issuing the SETSSI system console command

**Note:** The master subsystem (MSTR) is a part of z/OS and is not defined in any of these ways.

Some examples of IBM-supplied subsystems that use the subsystem interfaces (APIs) are the following:

- JES2 (primary or secondary subsystem) or JES3 (primary subsystem)
- IMS (secondary subsystem)
- NetView® (secondary subsystem)
Types of subsystems
There are four types of subsystems:

- The master scheduler subsystem is used to establish communication between the operating system and the primary job entry subsystem, which can be JES2 or JES3. It is also used to initialize system services such as the system log and communications task.
- The primary subsystem is the job entry subsystem that z/OS uses to receive jobs and STC. It can be exclusively either JES2 or JES3.
- Secondary subsystems provide functions as needed by IBM or vendor products, or the installation.
- Functional subsystems: JES2/JES3 allows certain functions to operate outside the JES2/JES3 address space. JES does this using:
  - The functional subsystem address space (FSS)
  - The functional subsystem interface (FSI)
  - The functional subsystem application (FSA)

A JES FSS that deals with output services is one type of FSS. This particular FSS address space can be created automatically or established by an operator command for a printer device which is capable of running under the control of an FSS address space. The operator command designates a printer.

All subsystem callers communicate with the subsystem through an API called the subsystem interface (SSI). MVS communicates with subsystems through the SSI.

Subsystem interface (SSI)
The SSI is the interface used by routines (IBM, vendor, or installation-written) to request services of, or to pass information to, subsystems. An installation can design its own subsystem and use the SSI to monitor subsystem requests. An installation can also use the SSI to request services from IBM-supplied subsystems. The SSI acts only as a mechanism for transferring control and data between a requestor and the subsystem; it does not perform any subsystem functions itself.

Unique attributes of the SSI
The SSI is a way for one routine to call another routine (contained in the subsystem). There are a number of other ways that a routine can call another routine, such as:

- Branch and link register (BALR 14,15)
- LINK or LINKX macro, through z/OS Program Management component
- Program call (PC), through cross memory
- SVC, through an SVC interruption passing the control to z/OS kernel

The SSI is different from these linkage interfaces, however, in that:

- The called routine does not have to be there. That is, when an SSI caller routine calls the subsystem, the SSI checks to see if the subsystem either is not interested in the request or does not exist. The SSI caller then receives an appropriate return code.
- An SSI caller’s request can be routed to multiple routines from the same subsystem.

Refer to “Subsystem interface (SSI)” on page 110, for more information about the SSI.
2.2 Subsystem initialization

- **Primary Subsystem**
  - JES2
  - JES3

- **Subsystem Initialization**

  ![Subsystem Initialization Diagram]

  *Figure 2-2  Subsystem initialization*

**The primary subsystem**

In order to process jobs and STC address spaces, z/OS requires that at least one subsystem be defined as a primary job entry subsystem (JES) to receive jobs into the system. You can select either JES2 or JES3. If you do not specify an IEFSSNxx member in SYS1.PARMLIB, z/OS attempts to use the system default member, IEFSSN00. IEFSSN00, as supplied by IBM, contains the definition for the default primary job entry subsystem, JES2.

If you attempt to IPL without specifying an IEFSSNxx member, and IEFSSN00 is not present or does not identify the primary subsystem, the IPL code issues message IEFJ005I and prompts the operator for the primary subsystem.

Do not define a subsystem more than once in a combination of IEFSSNxx members that can be used together in an IPL. The same subsystem can appear in two different IEFSSNxx members when the members are not used together.

**How to initialize your subsystem**

Subsystem initialization means to call specific routines that prepare the subsystem to receive SSI calls. The SSVT as pictured in the Figure 2-2 is explained in “SSI control blocks and routines” on page 111. There are two ways to initialize your subsystem:

- Specifying an initialization routine at IEFSSNxx
- Using the START command
You can also combine these methods, doing part of the setup through an initialization routine, then completing initialization through a START command.

**Specifying an initialization routine**

You can optionally specify the name of your subsystem initialization routine when you define your subsystem. If the functions the subsystem supplies might be needed during the IPL process, define your initialization routine in IEFSSNxx. In this case, the initialization routine handles all the preparation to ensure the subsystem is active.

**Using the START command**

If the subsystem functions are not needed until a later time after the IPL, you can use the START command to invoke your programs to initialize your subsystem. See *z/OS MVS System Commands, SA22-7627-04* and *z/OS MVS JCL Reference, SA22-7597-04* for more information about the START command.
2.3 Types of subsystem requests

Subsystem requests
The SSI handles two types of subsystem caller requests: directed requests and broadcast requests.

The SSI is different from the linkage interfaces, however, in that:

- The called routine does not have to be there. That is, when a routine calls the subsystem, the SSI checks to see if the subsystem either is not interested in the request or does not exist. The caller then receives an appropriate return code.

- A caller’s request can be routed to multiple subsystem routines.

Directed requests
The left side of Figure 2-3 shows the processing for a directed request. Directed requests, which can be defined by the installation, are made to one named subsystem. For a directed request, the caller informs the named subsystem of an event, or asks the named subsystem for information. For example, you can access JES SYSOUT data sets with a directed request.

Broadcast requests
The right side of Figure 2-3 shows the processing for a broadcast request. Broadcast requests, which can only be called by a z/OS routine, provide the ability for subsystems to be informed when certain events occur in the system. Broadcast requests differ from directed requests in that the system allows multiple subsystems to be informed when an event occurs. The SSI gives control to each subsystem that is active and that has expressed an interest in
being informed of the event. For example, your subsystem can be informed when a WTOR message is issued in order to automate a response to the WTOR.

**Controlling SSI requests**
The IEFJFRQ installation exit provides a way to examine and modify subsystem function requests. See *z/OS MVS Installation Exits*, SA22-7593-04 for more information on the capabilities and use of the IEFJFRQ exit.
2.4 IEFSSNxx parmlib member

IEFSSNxx (subsystem definitions)

IEFSSNxx contains parameters that define the primary subsystem and the various secondary subsystems that are to be initialized during system initialization.

IEFSSNxx allows you to:

- Specify a primary subsystem name and whether you want it started automatically.
- Name the subsystem initialization routine to be given control during master scheduler initialization.
- Specify the input parameter string to be passed to the subsystem initialization routine.

For information about writing subsystems, see z/OS MVS Using the Subsystem Interface, SA22-7642-01.

The order in which the subsystems are initialized depends on the order in which they are defined in the IEFSSNxx parmlib member on the SSN parameter. The SMS subsystem must be initialized first. Second is the primary subsystem (JES2 or JES3). Some subsystems require the services of the primary subsystem in their initialization routines. Problems can occur if subsystems that use the subsystem affinity service in their initialization routines are initialized before the primary subsystem.

**Note:** In general, it is a good idea to use the first four characters of the subsystem name as the name of the JCL member of the SYS1.PROCLIB used to start the subsystem.
Restrictions for IEFSSNxx

The entries in the IEFSSNxx could be in either of two formats: positional or keyword. These two formats cannot be mixed in one IEFSSNxx. It is strongly recommended to use the keyword format. Only subsystems that have been defined using the keyword format IEFSSNxx parmlib member can be dynamically modified by IEFSSI macro, or the SETSSI ADD system console command:

- **Macros**
  - IEFSSI REQUEST=ACTIVATE
  - IEFSSI REQUEST=DEACTIVATE
  - IEFSSI REQUEST=OPTIONS
  - IEFSSI REQUEST=SWAP
  - IEFSSI REQUEST=GET
  - IEFSSI REQUEST=PUT
  - IEFSSVT

- **System commands**
  - SETSSI ACTIVATE
  - SETSSI DEACTIVATE

Repeating, you cannot use dynamic SSI services for subsystems defined with the positional form of this member.
2.5 Subsystem definitions

SYS1.PARMLIB: IEFSSNxx

[CONSNAME(consname)]
[INITRTN(initrtn)]
[INITPARM(initparm)]
[PRIMARY(YES)]
[START(YES)]

SYS1.PARMLIB: IEASYSxx SSN=xx

Figure 2-5  Subsystem definitions

Statements and parameters for IEFSSNxx

As we already mentioned, the storage management subsystem (SMS) is the only subsystem that can be defined before the primary subsystem. Refer to the description of parmlib member IEFSSNxx in z/OS V1R4.0 MVS Initialization and Tuning Reference, SA22-7592-03, for SMS considerations. The statements and parameters for IEFSSNxx are:

SUBSYS  The statement that defines a subsystem that is to be added to the system. If more than one SUBSYS statement appears for the same subsystem name, the first statement will be the one used to define the subsystem. The duplicate statements will be rejected with a failure message that is sent to the console.

SUBNAME  The subsystem name. The name can be up to four characters long; it must begin with an alphabetic or special character (#, @, or $), and the remaining characters (if any) can be alphanumeric or special.

CONSNAME  The name of the console to which any messages that the SSI issues as part of initialization processing are to be routed. This name is optional and can be two to eight characters long. This console name is also passed to the routine named on the INITRTN keyword if it is specified. The default is to issue messages to the master console.

INITRTN  The name of the subsystem initialization routine. This name is optional and can be one to eight characters long. The first character can be either alphabetic or special. The remaining characters can be either alphanumeric
or special. The routine receives control in supervisor state key 0. It must be the name of a load module stored in SYS1.LINKLIB.

INITPARM Input parameters to be passed to the subsystem initialization routine. The input parameters are optional and are variable in length, to a maximum of 60 characters. The INITPARM keyword can only be specified if the INITRTN keyword is specified.

PRIMARY This parameter, ([NO|YES]), indicates whether this is the primary subsystem. The primary subsystem is typically a job entry subsystem (either JES2 or JES3). This parameter is optional. Initialize the primary subsystem before any secondary subsystems except SMS. If you specify PRIMARY on more than one statement, the system issues message IEFJ008I and defines the second subsystem, but ignores the PRIMARY specification. The IEFSSNxx parmlib member is the only place you can define the primary subsystem. It cannot be defined using the dynamic SSI services IEFSSI REQUEST=ADD macro or the SETSSI ADD command. The default is NO.

START This parameter, ([YES|NO]), indicates whether an automatic START command should be issued for the primary subsystem.

If the parmlib entry for the primary subsystem is START(NO), the operator must start it later with a START command. If the parmlib entry for the primary subsystem does not specify the START parameter, it defaults to START(YES).

The START parameter cannot be specified for a secondary subsystem. If you specify the PRIMARY(NO) parameter, there is no default for the START parameter.

Subsystem example
Define subsystem JES2 as a primary subsystem and the START command to be issued by the system. No initialization routine is required because subsystem JES2 builds the SSVT when the START command is issued.

SUBSYS SUBNAME(JES2) PRIMARY(YES)

Parameter in IEASYSxx (or specified by the operator)
The SSN parameter in IEASYSxx identifies the IEFSSNxx member that the system is to use to initialize the subsystems, as follows:

\[
\text{SSN} = \{ \text{aa} \} \cup \{ \text{aa,bb,...} \}
\]

The two-character identifier, represented by aa (or bb, and so forth) is appended to IEFSSN to identify IEFSSNxx members of parmlib. If the SSN parameter is not specified, the system uses the IEFSSN00 parmlib member. The order in which the subsystems are defined on the SSN parameter is the order in which they are initialized. For example, a specification of SSN=(13,Z5) would cause those subsystems defined in the IEFSSN13 parmlib member to be initialized first, followed by those subsystems defined in the IEFSSNZ5 parmlib member. If you specify duplicate subsystem names in IEFSSNxx parmlib members, the system issues message IEFJ003I to the SYSLOG, the master console, and consoles that monitor routing code 10 messages.

Some exits that use system services may run before other system address spaces are active. You must ensure that any address spaces required by the system services are available prior to invoking the service. For more information, see the section on handling errors in defining your subsystem in z/OS MVS Using the Subsystem Interface, SA22-7642.
2.6 Subsystem interface (SSI)

- **Means of communication between:**
  - System and subsystem

- **Consists of:**
  - Control blocks - macros - routines
  - SSIB - SSOB - IEFSSREQ - PLPA modules

**Subsystem Interface (SSI)**

The SSI is an API that provides communication between a subsystem caller routine (IBM, vendor, or installation-written) and the subsystem through the IEFSSREQ macro. The reason for such communication is to request services of, or to pass information to subsystems. An installation can design its own subsystem and use the SSI to monitor subsystem requests. An installation can also use the SSI to request services from IBM-supplied subsystems. The SSI does not perform any subsystem functions itself – it is just an API.

**IEFSSREQ macro requests**

For example z/OS components such as the initiator issue the IEFSSREQ macro to invoke JES asking for a job to be executed.

**Control blocks**

The calling routine uses a subsystem identification block (SSIB) to identify the specific subsystem and a subsystem option block (SSOB) to identify the function to be executed by the subsystem. You must tell the SSI the function you are requesting and the subsystem with which you want to communicate. You make a request by obtaining storage for the following control blocks:

- SSOB that specifies the function code
- SSOB function dependent area (if required) for each function code
- SSIB that specifies the subsystem name that is to perform the function
2.7 SSI control blocks and routines

SSI control blocks

The z/OS nucleus contains a control block named the JES control table (JESCT). This block contains a pointer to the subsystem communication vector table (SSCVT), which is located in CSA. There is one entry in the SSCVT per each defined subsystem in this z/OS. There are always at least two SSCVTs, one of which represents the z/OS master subsystem and the other the primary subsystem.

The IEFSSREQ macro provides the communication between the subsystem caller and the subsystem itself. The calling routine uses the subsystem option block (SSOB) and subsystem identification block (SSIB) to identify the required processing to the subsystem. The SSIB is an index in the SSCVT indicating the specific subsystem. Each SSCVT entry (corresponding to one subsystem) points to an SSVT. Each SSVT has an entry per each possible function that the subsystem owner of the SSVT can execute. The SSOB is an index into the SSVT, then indicating the required function. Recapping the control blocks involved:

- **JESCT**  JES control table (JESCT). A control block in the z/OS nucleus that contains information used by subsystem interface routines.
- **SSCVT**  Subsystem communication vector table (SSCVT). This control block is the common storage area that contains information about each defined and active subsystem.
- **SSVT**  The subsystem vector table (SSVT). The SSVT resides in the common service area (CSA) and contains one entry per each possible subsystem function.
2.8 SSI request to master subsystem

Master subsystem requests
The IEFJSREQ routine checks the validity of the SSOB and SSIB; the request routine determines that the target subsystem exists and is started. It next uses the function code to determine if the subsystem performs the requested function and to derive the address of a routine to which the request is to be passed. The SSOB is associated with the function code requested by the caller and the SSIB is associated with the subsystem to perform the function requested.

There are 15 different SSI functions supported by the master subsystem, but several of the routines perform more than one function.

The SSVT contains a matrix of the function codes and in the visual the first function code supported by the MSTR subsystem is function code 4. The number 4 shown in the fourth position indicates that the routine that gets control is the fourth routine pointer (ptr) shown after the function code matrix in the SSVT.

For example, function code 15 in the master subsystem (MSTR) is used to verify the subsystem (JES) name when JES initializes, and is the third routine pointer, as function code 15 has a 3 in the matrix.

Chapter 3. Job management

z/OS job management in a z/OS system uses a job entry subsystem (JES) to receive jobs into the operating system, schedule them for processing by z/OS, and control their output processing. JES provides supplementary job management, data management, and task management functions such as: scheduling, control of job flow, and spooling. JES is designed to provide efficient spooling, scheduling, and management facilities for the z/OS system.

For a program to execute on the computer and perform the work it is designed to do, the program must be processed by the operating system. The operating system consists of a base control program (BCP) with a job entry subsystem (JES2 or JES3) and DFSMSdfp™ installed with it.

For the operating system to process a program, programmers must perform certain job control tasks. These tasks are performed through the job control statements (JCL). The job control tasks are performed by the JES and are:

- Entering jobs
- Processing jobs
- Requesting resources
3.1 z/OS and job management

- Understanding JCL
- Job control statements
- Required JCL statements
- Why JES?

Figure 3-1 z/OS and job management

z/OS and job management

A major goal of an operating system is to process jobs while making the best use of system resources. To achieve that goal, the operating system does resource management, which consists of the following:

- Before job processing, reserve input and output resources for jobs
- During job processing, manage resources such as processors and storage
- After job processing, free all resources used by the completed jobs, making the resources available to other jobs

Understanding JCL

To get your MVS system to do work for you, you must describe to the system the work you want done and the resources you will need. You use JCL to provide this information to MVS. Refer to ABCs of z/OS System Programming Volume 1, SG24-6981 for a description of JCL and how it works.

To get your MVS system to do work for you, you must describe to the system the work you want done and the resources you will need. You use Job Control Language (JCL) to provide this information to MVS. At any instant, a number of jobs can be in various stages of preparation, processing, and post-processing activity. To use resources efficiently, the operating system distributes jobs into queues to wait for needed resources according to their stages, such as: conversion queue, waiting execution queue, processing queue, output
The function of keeping track of which job is in which queue is called workflow management.

The MVS system shares the management of jobs and resources with a JES. JES does job management and resource management before and after job execution, while MVS does it during job execution. The JES receives jobs into MVS, schedules them for processing by MVS, and controls their output processing.

**Jobs and JCL**

For every job that you submit, you need to tell MVS where to find the appropriate input, how to process that input (that is, what program or programs to run), and what to do with the resulting output. You use JCL to convey this information to MVS through a set of statements known as job control statements. JCL's set of job control statements is quite large, enabling you to provide a great deal of information to MVS.

**Required control statements**

Every job must contain a minimum of the following two types of control statements:

- A JOB statement, to mark the beginning of a job and assign a name to the job. The JOB statement is also used to provide certain administrative information, including security, accounting, and identification information. Every job has one and only one JOB statement.

- An EXEC (execute) statement, to mark the beginning of a job step, to assign a name to the step, and to identify the program or procedure to be executed in the step. You can add various parameters to the EXEC statement to customize the way the program executes. Every job has at least one EXEC statement.

In addition to the JOB and EXEC statements, most jobs usually also contain:

- One or more DD (data definition) statements, to identify and describe the input and output data to be used in the step. The DD statement may be used to request a previously created data set, to define a new data set, to define a temporary data set, or to define and specify the characteristics of the output.
3.2 Job management

Job Management
As shown in Figure 3-2 and described in volume 1, you can submit a job from a TSO/E terminal to JES2 or JES3 using internal readers. Jobs are submitted to different classes of execution according to the CLASS parameter.

Figure 3-2 shows the methods by which jobs can be submitted; Figure 3-3 shows an overview of the job submission process. The user performs the activities shown on the left side of the figure; the system performs those on the right. In this figure, z/OS and JES comprise the “system.”

Internal readers
The internal reader is a software substitute for a card punch and a card reader, a tape drive, or a TSO/E terminal. Instead of entering a job into the system (through JES) on punched cards, or through tape, you can use the output of one job or step as the input to another job, which JES will process directly.

The internal reader facility is useful for several kinds of applications:
- You can use it to generate another job or a series of jobs from an already-executing job. An online application program can submit another job to produce a report, for example, so it does not have to do it itself.
A job that produces a series of jobs can put its output to an internal reader for immediate execution. For example, a job that updates databases and starts other applications based upon some input parameters or real-time events can use the internal reader for its output.
3.3 JCL-related actions

For your program to execute on the computer and perform the work you designed it to do, your program must be processed by your operating system. Your operating system consists of an MVS base control program (BCP) with a job entry subsystem (JES2 or JES3) and DFSMSdfp installed with it.

For the operating system to process a program, programmers must perform certain job control tasks. These tasks are performed through the job control statements, which consist of:

- JCL statements
- JES2 control statements
- JES3 control statements

In general, statements in the MVS Job Control Language (JCL) and in the Job Entry Control Language (JECL) for JES2 and JES3 subsystems are used by the users to define a job's execution steps and resource requirements. The MVS system creates an internal format of the job's JCL statements before it can process it. MVS converter/interpreter transforms the external (JCL) format job description into the internal format called the scheduler work area (SWA). Whatever the source of the input, JES is signalled that an input stream is to be read. This begins a chain of events that includes deciding where the job executes and creates output data sets that later are processed by JES to the output devices.

Figure 3-4  JES2 and JES3 main differences

JES differences
You can choose between two options for your primary JES: JES2 and JES3.

If your installation has only one MVS image, then both JES2 and JES3 perform similar functions, with JES3 providing additional functions related to job scheduling. The common functions executed by both JESes are reading jobs into the system, converting them to internal machine-readable form, select them for processing, processing their output, and purging them from the system.

If your installation has more than one MVS image in a configuration, then the scheduling functions of JES3 are a big advantage. If you have more than one MVS image and you are running JES2, then JES2 in each MVS image exercises independent control over its job processing functions. That is, within the configuration, each JES2 processor controls its own job input, job scheduling, and job output processing.

In a JES3 environment, however, one MVS image hosts a JES3 that performs centralized control over its and the other MVS images’ functions. This JES3 is called JES3 global processor; the JES3 instances in the other MVS images are called JES3 local processors.

It is from the global processor that JES3 manages jobs and resources for the entire complex, matching jobs with available resources. JES3 ensures that they are available before selecting the job for processing.

To better understand the functional differences between JES2 and JES3, refer to z/OS JES2 Initialization and Tuning Guide, SA22-7532, and z/OS JES3 Initialization and Tuning Guide, SA22-7549.
3.5 JES2 primary job entry subsystem

What is JES2?
MVS uses a JES to receive jobs into the operating system, schedule them for processing by MVS, and control their output processing. JES2 is descended from HASP (Houston automatic spooling priority). HASP is defined as a computer program that provides supplementary job management, data management, and task management functions such as scheduling, control of job flow, and spooling. HASP remains within JES2 as the prefix of most module names and the prefix of all messages sent by JES2 to the operator.

JES2 is a functional extension of the HASP II program that receives jobs into the system and processes all output data produced by the job. So, what does all that mean? Simply stated, JES2 is that component of MVS that provides the necessary functions to get jobs into, and output out of, the MVS system. It is designed to provide efficient spooling, scheduling, and management facilities for the MVS operating system.

But, none of this explains why MVS needs a JES. Basically, by separating job processing into a number of tasks, MVS operates more efficiently. At any point in time, the computer system resources are busy processing the tasks for individual jobs, while other tasks are waiting for those resources to become available. In its most simple view, MVS divides the management of jobs and resources between the JES and the base control program of MVS. In this manner, JES2 manages jobs before and after running the program; the base control program manages them during processing.

The following sections describe each JES2 function identified in Figure 3-5.
3.6 JES2 functions

JES2 job flow
During the life of a job, both JES2 and the base control program of MVS control different phases of the overall processing. Generally speaking, a job goes through the following phases:

- Input
- Conversion
- Processing
- Output
- Print/punch (hard copy)
- Purge

Except for processing, all the job phases are controlled by JES2.

JES2 functional areas
To manage job input/output, JES2 controls a number of functional areas, all of which you can customize according to your installation's need. Some of the major functional areas and processing capabilities are:

- Getting work into and out of MVS (input/output control):
  
  JES2 controls output and input devices such as local and remote printers, punches, and card readers. You define each device to JES2 using JES2 initialization statements. All are directly under JES2's control with the exception of those printers that operate under the Print Services Facility™ (PSF). Printed and punched output can be routed to a variety of
devices in multiple locations. The control JES2 exercises over its printers ranges from the job output classes and job names from which the printer can select work, to specifications such as the forms on which the output is printed. This control allows the system programmer to establish the job output environment most efficiently without causing unnecessary printer backlog or operator intervention. Through JES2, the installation defines the job input classes, reader specifications, and output device specifications. As a result, JES2 is the central point of control over both the job entry and job exit phases of data processing. As shown in Figure 3-6 on page 123, you can also enter jobs to JES2 using TSO/E or any other product that can read jobs from a data set and pass them to JES2 via internal reader.

- Maximizing efficiency through job selection and scheduling:

JES2 allows the installation to define work selection criteria. It can be specific for each output device (local and remote printers and punches and offload devices). The work selection criteria are defined in the device initialization statements and can be changed dynamically using JES2 commands. You can define:

- Specification of job and output characteristics that JES2 considers when selecting work for an output device
- Priority of the selection characteristics
- Characteristics of the printer and job that must match exactly

A job's output is grouped based on the data set's output requirements. The requirements may be defined in the job's JCL or by JES2-supplied defaults.

When selecting work to be processed on a device, JES2 compares the device characteristics with the output requirements. If they match, JES2 sends the output to the device. If they do not match, JES2 does not select the work for output until the operator changes the device characteristics or the output requirements.

- Offloading work and backing up system workload:

JES2 gives your installation the capability to offload data from the spool and later reload data to the spool. This is useful if you need to:

- Preserve jobs and SYSOUT across a cold start
- Migrate your installation to another release of JES2
- Convert to another DASD type for spool
- Archive system jobs and SYSOUT
- Relieve a full-spool condition during high-use periods
- Provide a backup for spool data sets
- Back up network connections

JES2 offers many selection criteria to limit the spool offload operation. These selection criteria can be changed by operator command, according to initial specification in the JES2 initialization statements.

- System security:

JES2 provides a basic level of security for resources through initialization statements. That control can be broadened by implementing several JES2 exits available for this purpose. A more complete security policy can be implemented with System Security Facility (SAF) and a security product such as RACF.

- Supporting advanced function printers (AFPs)

JES2 is responsible for all phases of job processing and monitors the processing phase. The base control program (BCP) and JES2 share responsibility in the z/OS system. JES2 is responsible for job entry (input), the base control program for device allocation and actual job running, and finally JES2 for job exit (output). Figure 3-7 on page 125 presents an overview of the job phases.
3.7 JES2 job flow

Job processing phases
The six phases of job processing are as follows:

1. **Input phase**: JES2 accepts jobs, in the form of an input stream, from input devices, internal readers, other nodes in a job entry network, and from other programs. The internal reader is a program that other programs can use to submit jobs, control statements, and commands to JES2. Any job running in MVS can use an internal reader to pass an input stream to JES2. JES2 can receive multiple jobs simultaneously through multiple internal readers. MVS uses internal readers, allocated during system initialization, to pass to JES2 the JCL for started tasks, START and MOUNT commands, and TSO LOGON requests.

   The system programmer defines internal readers to be used to process all batch jobs other than STCs and TSO requests. These internal readers are defined in JES2 initialization statements and JES2 allocates them during JES2 initialization processing. The internal readers for batch jobs can be used for STCs and TSO requests, if not processing jobs. JES2 reads the input stream and assigns a job identifier to each job JCL statement. JES2 places the job's JCL, optional JES2 control statements, and SYSIN data onto DASD data sets called spool data sets. JES2 then selects jobs from the spool data sets for processing and subsequent running.

2. **Conversion phase**: JES2 uses a converter program to analyze each job's JCL statements. The converter takes the job's JCL and merges it with JCL from a procedure library. The procedure library can be defined in the JCLLIB JCL statement, or system/user procedure libraries can be defined in the PROCxx DD statement of the JES2 startup procedure. Then, JES2 converts the composite JCL into converter/interpreter text that
both JES2 and the job scheduler functions of MVS can recognize. Next, JES2 stores the converter/interpreter text on the spool data set. If JES2 detects any JCL errors, it issues messages, and the job is queued for output processing rather than run. If there are no errors, JES2 queues the job for execution.

3. **Processing phase:** In the processing phase, JES2 responds to requests for jobs from the MVS initiators. An initiator is a system program that is controlled by JES or by WLM (in goal mode, with WLM Batch Initiator Management). JES2 initiators are defined to JES2 through JES2 initialization statements. JES2 initiators are started by the operator or by JES2 automatically when the system initializes. The installation associates each initiator with one or more job classes in order to obtain an efficient use of available system resources. Initiators select jobs whose classes match the initiator assigned class, obeying the priority of the queued jobs.

WLM initiators are started by the system automatically based on the performance goals, relative importance of the batch workload, and the capacity of the system to do more work. The initiators select jobs based on their service class and the order they were made available for execution. Jobs are routed to WLM initiators via a JOBCLASS JES2 initialization statement. In goal mode, with WLM Batch Management, a system can have WLM initiators and JES2 initiators.

After a job is selected, the initiator invokes the interpreter to build control blocks from the converter/interpreter text that the converter created for the job. The initiator then allocates the resources specified in the JCL for the first step of the job. This allocation ensures that the devices are available before the job step starts running. The initiator then starts the program requested in the JCL EXEC statement.

JES2 and the MVS Basic Control Program (BCP) communicate constantly to control system processing. The communication mechanism, known as the subsystem interface, allows MVS to request services of JES2. For example, a requestor can ask JES2 to find a job, message or command processing, or open (access) a SYSIN or SYSOUT data set. Further, the base control program notifies JES2 of events such as messages, operator commands, the end of a job, or the end of a task. By recognizing the current processing phase of all jobs on the job queue, JES2 can manage the flow of jobs through the system.

4. **Output phase:** JES2 controls all SYSOUT processing. SYSOUT is a data set in a printer device format, that is, it is ready to be printed. Intermediately, a sysout file is stored in the spool data set. There are many advantages in spooling a sysout to JES, such as faster processing (DASD is faster than a printer), optimization of the printer devices, and spool backup and archive. MVS directs to sysout system messages related to job execution.

After a job finishes, JES2 analyzes the characteristics of the job's output in terms of its output class and device setup requirements; then JES2 groups data sets with similar characteristics. JES2 queues the output for print processing.

5. **Hardcopy phase:** JES2 selects output for processing from the output queues by output class, route code, priority, and other criteria. The output queue can have output to be processed locally or output to be processed at a remote location (either an RJE workstation or another node). After processing all the output for a particular job, JES2 puts the job on the purge queue.

6. **Purge phase:** When all processing for a job completes, JES2 releases the spool space assigned to the job, making the space available for allocation to subsequent jobs. JES2 then issues a message to the operator indicating that the job has been purged from the system.
3.8 JES2 spool data sets

JES2 spool data sets
JES2 maintains copies of its data sets that contain job and output queues (that is, lists of jobs to be processed by MVS) on direct access storage devices (DASD). Future work is added to these queues and JES2 selects work for processing from them. These data sets and queues must remain current and accurate to maintain system integrity and performance. The following is a discussion of the JES2 spool and checkpoint data sets and the processing JES2 uses to maintain them.

Spool data sets and spooling
Simultaneous peripheral operations online (spool) has several meanings as used in this book and throughout JES2 documentation. Spooling is a process by which the system manipulates its work. This includes:

- Using storage on direct access storage devices (DASD) as a buffer storage to reduce processing delays when transferring data between peripheral equipment and a program to be run.
- Reading and writing input and output streams on an intermediate device for later processing or output.
- Performing an operation such as printing while the computer is busy with other work.

Spool also refers to the direct access device that contains the spool data sets. This definition is generally apparent from the context of its use and should not cause any misunderstanding in the following sections of this book or other JES2 documentation.
Spooling is critical to maintain performance in the MVS-JES2 environment. JES2 attempts to maximize the performance of spooling operations, which ultimately benefits the throughput of work through the JES2 installation.

As noted previously, spooling provides simultaneous processing and a temporary storage area for work that is not yet completed. Once JES2 reads a job into the system, JES2 writes the job, its JCL, its control statements, and its data to a spool data set until further processing can occur.

For these reasons, spooling is critical to maintain performance in the MVS-JES2 environment.
3.9 JES2 checkpoint data set

- Backup of the jobs and output queues
- Accessible for all member of the MAS complex
- Communication among all members in the MAS
- Maintain system integrity

Figure 3-9  JES2 checkpoint data set

JES2 checkpoint data set

Errors can occur while processing jobs and data. Some of these errors can result in the halting of all system activity. Other errors can result in the loss of jobs or the invalidation of jobs and data. If such errors occur, it is preferable to stop JES2 in a way that allows processing to be restarted with minimal loss of jobs and data. The checkpoint data set, checkpointing, and the checkpoint reconfiguration dialog all help to make this possible.

The checkpoint is the data set that JES2 maintains on either DASD or a Coupling Facility that permits JES2 to perform two separate functions:

1. Job and output queue backup to ensure ease of JES2 restart, since it contains information about what work is yet to be processed and how far along that work has progressed.
2. In a multi-access spool (MAS) environment, member-to-member workload communication to ensure efficient independent JES2 operation.

JES2 periodically updates the checkpoint data set by copying the changed information from the in-storage copy to the checkpoint data set copy. Information in the checkpoint data set is critical to JES2 for normal processing and also if a JES2 or system failure occurs.

Taking checkpoints

Taking checkpoints is the periodic copying of a member's in-storage job and output queues to the checkpoint data set. In a MAS environment, checkpointing ensures that information about a member's in-storage job and output queues is not lost if the member loses access to these queues as the result of either hardware or software errors. Because all members in a JES2
MAS configuration operate in a loosely-coupled manner, each capable of selecting work from the same job and output queues, checkpointing allows all members to be aware of current queue status. Within the single-member environment, the checkpoint function operates solely as a backup to the “in-storage” job and output (SYSOUT) queues maintained by JES2.

Defining checkpoint configuration mode

There are three ways of specifying the checkpoint configuration mode. The type of mode you select depends upon your JES2 configuration:

- **DUPLEX-mode processing with backup:**
  JES2 can operate its checkpoint configuration in DUPLEX mode if you have defined two checkpoint data sets, a primary and a duplex. They can be either in DASD or a Coupling Facility. The duplex data set is updated once for every write to the primary. If the primary data set suffers an error, the duplex can provide either an exact duplicate of the primary or a very similar, almost current (depending on when it was last updated) copy of the checkpoint data.

  It is recommended that all members in the JES2 configuration operate, if possible, with DUPLEX=ON in the CKPTDEF. This provides the greatest protection from checkpoint error.

- **DUPLEX-mode processing without backup:**
  Processing with a single checkpoint data set is not recommended in most cases. If that data set becomes damaged, lost, or suffers an I/O error, and your member experiences a concurrent failure, you will not have a checkpoint data set available to restart JES2. But you have the benefit that JES2 will not need to read/write to two data sets. However, depending on your specific volume or structure use and configuration, it might not be practical for particular members of your JES2 configuration to maintain a backup checkpoint (for example, in systems that manage basically online transactions).

- **DUAL-mode processing:**
  This configuration also uses two data sets, but in a “flip-flop” scheme; that is, individual members do not always read and write to the same CKPTn data set. However, the member performing a read always uses the checkpoint data set last updated. This is not required in a single-member environment. However, it is recommended in a MAS environment, if the installation is suffering from degraded system performance due to high checkpoint data set I/O. The use of the change provides reduced I/O to the checkpoint data set during most, if not all, update accesses by a member of the multi-access spool configuration.

**Note:** This mode cannot be used if any checkpoint data set resides on a Coupling Facility structure.

Checkpoint reconfiguration dialog

JES2 provides a dynamic means by which the current checkpoint configuration can be changed. It is the checkpoint reconfiguration dialog, which can be initiated by the operator system or by JES2. JES2 will enter a checkpoint reconfiguration for any of these reasons:

- **To complete initialization processing:**
  - Either JES2 could not determine the checkpoint data set specifications, or JES2 requires operator verification of the data set specifications
  - JES2 startup option
  - Checkpoint statement definition
- **To correct an I/O error to the checkpoint data set**
- **To move the checkpoint off a volatile Coupling Facility structure**
### 3.10 JES2 configurations

</tbody>
</table>

**Figure 3-10  JES2 configurations**

**JES2 configurations**

The following are possible JES2 configurations:

- **Single-system configuration**
  
  A JES2 configuration can contain as few as one processor (one MVS and JES2 system) or as many as 32 processors linked together. A single processor is referred to as a single-system configuration. Such a system is suitable for an installation that has a relatively small work load, or possibly an installation that requires a single processor to be isolated from the remainder of the data processing complex (for example, to maintain a high degree of security).

- **Multiple-system configuration (MAS)**
  
  Many installations take advantage of JES2’s ability to link processors together to form a multiple-processor complex, which is generally referred to as a multi-access spool (MAS) configuration. A multi-access spool configuration consists of two or more JES2 (MAS) processors at the same physical location, all sharing the same spool and checkpoint data sets. There is no direct connection between the processors; the shared direct access data sets provide the communication link. Each JES2 processor can read jobs from local and remote card readers, select jobs for processing, print and punch results on local and remote output devices, and communicate with the operator. Each JES2 processor in a multiple processor complex operates independently of the other JES2 processors in the configuration.
The JES2 processors share a common job queue and a common output queue, which reside on the checkpoint data sets. These common queues enable each JES2 processor to share in processing the installation's workload; jobs can run on whatever processor is available and print or punch output on whatever processor has an available device with the proper requirements. Users can also specifically request jobs to run on a particular processor and output to print or punch on a specific device. If one processor in the configuration fails, the others can continue processing by selecting work from the shared queues and optionally take over for the failed processor. Only work in process on the failed processor is interrupted; the other JES2 systems continue processing.

- **Running multiple copies of JES2 (Poly-JES)**

  MVS allows more than one JES2 subsystem to operate concurrently, if one subsystem is designated as the primary subsystem and all others are defined as secondary subsystems. A secondary JES2 does not have the same capabilities as the primary JES2, and some restrictions apply to its use. Most notably, TSO/E users can only access the primary subsystem. The restrictions are necessary to maintain the isolation from the MVS-JES2 production system, but the convenience for testing is a valuable function. Operation of multiple copies of JES2 is referred to as poly-JES. Secondary JES2s can be useful in testing a new release or installation-written exit routines. This isolation prevents potential disruption to the primary JES2 and base control program necessary for normal installation production work.

- **JES2 remote job entry (RJE)**

  An RJE workstation is a workstation that is connected to a member by means of data transmission facilities. The workstation can be a single I/O device or group of I/O devices or can include a processor such as a z/Series machine. Generally, RJE workstations include a programmable workstation (such as a personal computer) connected to the MVS system through a telecommunication link. Such a link utilizes synchronous data link control (SDLC) or binary synchronous communication (BSC) protocols for communicating between JES2 and remote devices. The remote device will be either a system network architecture (SNA) remote, which uses SDLC, or a BSC remote, which uses BSC. Figure 3-11 on page 133 shows a simple RJE configuration.

- **JES2 network job entry (NJE)**

  The JES2 network job entry facility is similar to remote job entry (RJE) in that both provide extensions to a computer system. In its simplest terms, NJE is “networking” between systems that interact as peers, whereas RJE is networking between JES2 and workstations. The main difference between them is one of overall computing power and processor location. Remember, RJE is an extension of a single computer system (that is, either a single-processor or multi-access spool complex) that allows jobs to be submitted from, and output routed back to, sites that are remote to the location of that system. NJE provides a capability to link many such single-processor systems or multi-access spool complexes into a processing network. Each system can be located on the same physical processor, side-by-side in a single room, or across the world in a network of thousands of nodes. The important difference is that a processor and its local and remote devices make up a node. Two or more attached nodes make up an NJE network.
3.11 JES2 example of an RJE configuration

Figure 3-11 JES2 example of a RJE configuration

JES2 RJE configuration
An RJE workstation is an extension of the local processing facility, except that work is sent across teleprocessing lines. Sending work across teleprocessing lines is convenient for an installation that needs to provide many data entry points at remote locations or route output to many diverse locations. The following examples illustrate the use of RJE in two familiar daily business scenarios:

- In a large department store, many sales clerks need to print output on printers located at the many customer check-out desks throughout the store. Because the location of the building prevents direct connection to the MVS system located in the central office located several hundred miles away, each printer can be defined to JES2 as a remote printer.

- Consider a clothing store chain in which the store managers at seven different stores all need to place orders, access inventory, and provide billing information, all the information for which is maintained on storage devices located in the computer center at the main office. An individual store’s workstation is defined to JES2 as an SNA-attached remote to which the individual terminals are defined and as such become an extension of the JES2 configuration located at the main office.

As depicted in Figure 3-11, each of the clothing stores within a localized region of New York (the Hudson Valley towns of Highland, Hyde Park, Pleasant Valley, and so forth) is connected to the single processor located at the regional office in Poughkeepsie. One MVS/JES2 system conducts the business of inventory control, shipping, and billing for all of the stores in the region.
JES2 processes remote jobs in the same manner as those received from a local reader. (Local devices are printers, punches, card readers, and lines directly attached to the system without the need of transmission facilities.) The terminals and printers located in the Poughkeepsie office are locally attached; all other I/O devices (terminals and printers) in all the other branch stores are defined to JES2 as remote terminals and printers.

To provide RJE processing, the RJE workstation must be defined to the local processor. There are two protocols available by which JES2 can communicate with the RJE workstations: synchronous data link control (SDLC) and binary synchronous communication (BSC).

**RJE workstations**

An RJE workstation can have a processor, like the System/370™, that runs a JES2-generated program. The JES2-generated program allows the processor to send jobs to, and receive data from, JES2. Such RJE workstations have generally been replaced by either a programmable workstation (such as a personal computer) or a network job entry configuration, and they are rarely used in today's processing environment. Some RJE workstations do not have a processor. These workstations use a remote terminal, for example, a 2780 or 2770, to enter jobs into, and receive data from, JES2.

Refer to *z/OS JES2 Initialization and Tuning Guide*, SA22-7532 for a more complete discussion of RJE concepts.
3.12 JES2 example of an NJE configuration

**NJE configuration example**

The JES2 network job entry (NJE) facility is similar to remote job entry (RJE) in that they both provide extensions to a computer system.

NJE network nodes communicate (send and receive data) using various teleprocessing facilities. Nodes on the same physical processor use the Virtual Telecommunications Access Method (ACF/VTAM) program product to communicate; no hardware is required. Nodes located in the same room or building can utilize channel-to-channel adapters (CTCA) or telecommunication links. Nodes that are geographically dispersed utilize SNA or BSC telecommunication links. The following example further explains this concept.

If we return to the previous example of the clothing store chain, the Poughkeepsie regional office is the location of the processor (MVS and JES2); each of the sites (Highland, Hyde Park, Pleasant Valley, Fishkill, and so forth) is attached to the Poughkeepsie office as a remote site. Together, all the locations shown in Figure 3-11 comprise the Poughkeepsie node. For a locally owned, relatively small clothing store chain such as the one depicted, this complex may suffice. However, for a national clothier or one dealing in the import/export business, one processor would likely prove to be inadequate. Such a company would likely elect to establish many nodes throughout the world, each connected to all others in an NJE complex. Refer to Figure 3-12 for a diagrammatic view of such a network. Note that the different groups of the ordering/billing department and the business administration/payroll department can be separate members of a MAS making up the New York node.
Also note that the New York node is a multi-access spool configuration; Poughkeepsie is the configuration illustrated in Figure 3-11 on page 133, and all the other nodes located around the world (which are not depicted) are simple single-system configurations. In the network, a store manager in Pleasant Valley can order an item, the Poughkeepsie office (the main office for the Hudson Valley region) tallies the orders from this store and its other six stores and submits its order to the clothier chain headquarters located in New York City. The request and subsequent confirmation of the order is not instantaneous due to the distance and the traffic in the system but is a faster and a more efficient method of doing business than a telephone conversation, particularly if you further consider time zone differences. *Traffic* refers to the number of users, requests, jobs, and data currently being routed across available teleprocessing lines.
3.13 JES2 customization

- Meet installation's needs
  - Initialization data set
- IBM-defined exits
- Installation-defined exits
- Table pairs

**Figure 3-13 JES2 customization**

**JES2 customization**

JES2 is designed to be tailored to meet an installation's particular processing needs. You can address your basic customization needs when you create the JES2 initialization data set. If you find this control over JES2 processing to be insufficient, JES2 also provides exits and table pairs to change many JES2 functions or processes.

If you need to modify JES2 processing beyond the capability provided by initialization statements, and elect to do so through installation-written code, such code should be isolated from the IBM-shipped source code. Changes to JES2 processing implemented through direct source code modification are error prone, counter-productive during migration to future releases, and can prove to be very time-consuming when debugging, diagnosing, and applying IBM-written fixes (program temporary fixes (PTFs) and authorized program analysis report (APARs) fixes) to code. Further, alteration of JES2 processing in this manner complicates IBM service assistance. Therefore, JES2 provides several means of allowing you to tailor its processing without direct source code modification.

Recommended methods for tailoring JES2 processing include JES2 table pairs, IBM-defined exits, and installation-defined exits. A general discussion of each is provided later in this chapter. Refer to *z/OS JES2 Installation Exits*, SA22-7534-03 for a complete description of each IBM-defined exit.

**JES2 initialization data set**

Because every installation that uses JES2 to manage its work input and output is unique, so too are the requirements each installation has on JES2. To meet these needs, JES2 is highly tailorable, and with minimal effort, a system programmer can customize most JES2 functions by changing and using the JES2 initialization data set that is provided with the product in the HASIPARM member of the SYS1.AHASAMP data set. Although this data set will not run as
shipped without some installation additions, it is a valuable model that can save hours of system programmer input time.

With a set of approximately 70 initialization statements, you can control all JES2 functions. The JES2 initialization data set provides all the specifications that are required to define output devices (printers and punches), job classes, the JES2 spool environment, the checkpoint data sets, the trace facility, and virtually every other JES2 facility and function.

**JES2 initialization statements**

Each initialization statement groups initialization parameters that define a function. The use of most JES2 initialization statements is optional. That is, you need not define them unless you need to implement or tailor a particular function. Further, many of the parameters provide default specifications that allow your installation to perform basic JES2 processing with no explicit definition on your part. JES2 requires only a minimal set of initialization statements (and/or parameters) that you define when first installing JES2.

The JES2 initialization data set provides all the specifications that are required to define:

- Output devices (printers and punches)
- Job classes
- The JES2 spool environment
- The checkpoint data sets
- The trace facility
- Every other JES2 facility and function

In the IBM-provided sample data set, SYS1.VnRnMn.SHASSAMP, the HASI* members are samples you can tailor to meet your installation's needs.

JES2 initialization statements give the system programmer a single point of control to define an installation's policies regarding the degree of control users have over their jobs. For example, consider the confusion an installation would experience if users were allowed to define their own job classes and priorities. Very likely, all users would define all their jobs as top priority, resulting in no effective priority classifications at all.

JES2 provides an assortment of commands you can use to dynamically alter JES2 customization whenever your processing needs change. Table 3-1 identifies the available JES2 initialization statements.

**Table 3-1  JES2 initialization statements**

<table>
<thead>
<tr>
<th>Initialization statement</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>APPL(avvavvv)</td>
<td>Defines an SNA NJE application to JES2.</td>
</tr>
<tr>
<td>BADTRACK</td>
<td>Specifies an address or range of addresses of defective spool volume tracks JES2 is not to use.</td>
</tr>
<tr>
<td>BUFDEF</td>
<td>Defines the local JES2 buffers to be created.</td>
</tr>
<tr>
<td>CKPTDEF</td>
<td>Defines the JES2 checkpoint data set(s) and the checkpointing mode.</td>
</tr>
<tr>
<td>COMPACT</td>
<td>Defines a compaction table for use in remote terminal communications.</td>
</tr>
<tr>
<td>CONDEF</td>
<td>Defines the JES2 console communication environment.</td>
</tr>
<tr>

<tr>
<td>NAME</td>
<td>Specifies the module or control section to be modified through subsequent VER and REP initialization statements.</td>
</tr>
<tr>
<td>NETACCT</td>
<td>Specifies a network account number and an associated local account number.</td>
</tr>
<tr>
<td>NJEDEF</td>
<td>Defines the network job entry characteristics of this JES2 node.</td>
</tr>
<tr>
<td>NODE(nnnn)</td>
<td>Specifies the characteristics of the node to be defined.</td>
</tr>
<tr>
<td>OFF(n).JR</td>
<td>Specifies the characteristics of the offload job receiver associated with an individual offload device.</td>
</tr>
<tr>
<td>OFF(n).JT</td>
<td>Specifies the characteristics of the offload job transmitter associated with an individual offload device.</td>
</tr>
<tr>
<td>OFF(n).SR</td>
<td>Specifies the characteristics of the offload SYSOUT receiver associated with an individual offload device.</td>
</tr>
<tr>
<td>OFF(n).ST</td>
<td>Specifies the characteristics of the offload SYSOUT transmitter associated with an individual offload device.</td>
</tr>
<tr>
<td>OFFLOAD(n)</td>
<td>Specifies the characteristics of the logical offload device.</td>
</tr>
<tr>
<td>OPTSDEF</td>
<td>Defines the options that are currently in effect.</td>
</tr>
<tr>
<td>OUTCLASS(v)</td>
<td>Specifies the SYSOUT class characteristics for one or all output classes.</td>
</tr>
<tr>
<td>OUTDEF</td>
<td>Defines the job output characteristics of the JES2 member.</td>
</tr>
<tr>
<td>OUTPRTY(n)</td>
<td>Defines the association between the job output scheduling priorities and the quantity (records or pages) of output.</td>
</tr>
<tr>
<td>PCEDEF</td>
<td>Specifies the definition for various JES2 processes.</td>
</tr>
<tr>
<td>PRINTDEF</td>
<td>Defines the JES2 print environment.</td>
</tr>
<tr>
<td>PROCLIB</td>
<td>Ensures that data sets specified can be allocated.</td>
</tr>
<tr>
<td>PRT(nnnn)</td>
<td>Specifies the characteristics of a local printer.</td>

</tbody>
</table>
Chapter 3. Job management

For more information, refer to z/OS JES2 Initialization and Tuning Reference, SA22-7533 and z/OS JES2 Initialization and Tuning Guide, SA22-7532.

When you are first getting started, you need not define or even be concerned about some of the more sophisticated processing environments such as a multi-access spool complex, nodes, or remote workstations. You are simply building a base on which your installation can grow. There is no need to be overwhelmed with the potential complexity of your JES2 system.

As your installation grows, you will likely use more and more of JES2's available functions. The sample data set shipped in SYS1.PARMLIB contains all default values and requires only the addition of installation-defined devices and installation-specific values. It contains all the JES2 initialization statements and the defaults for all parameters for which they are provided.

### JES2 table pairs

Table pairs provide a facility to change, delete, or add to JES2 processing and/or function. Changes made to JES2 processing using table pairs are generally less prone to error than are changes made through installation exits. This is true because JES2 macros generate the tables and generally require you to write less code to be run.

A number of JES2 functions (such as initialization statement processing, command processing, and message building) use tables. You can customize these JES2 functions, and others, by extending their associated tables. JES2 examines two tables, known as a table pair. The first table (the JES2 table) provides the default processing specifications; the second table (the user table) is used to extend, change, or delete the default processing specifications. For example, you can add your own JES2 commands and messages, add a new initialization statement or parameter, abbreviate the length of a JES2 command, or delete an unnecessary command to prevent its accidental misuse.

To simplify the use of this facility you can use the JES2 default tables as templates for construction of installation-written tables. Depending on the table(s) from which you choose to add, change, or delete, using table pairs generally takes less detailed knowledge of JES2 internal structure than does writing an exit.

Table pairs do not replace the need for exits. Table pairs and exit points can provide added capability either independently or in conjunction with one another.

3.14 JES2 exits

JES2 exits

JES2 may not satisfy all installation-specific needs at a given installation. When you modify JES2 code to accomplish your specific functions, you are susceptible to the migration and maintenance implications that result from installing new versions of JES2. JES2 exits allow you to modify JES2 processing without directly affecting JES2 code. In this way, you keep your modifications independent of JES2 code, making migration to new JES2 versions easier and making maintenance less troublesome.

- Initialization processing
  You can modify the JES2 initialization process and incorporate your own installation-defined initialization statements in the initialization process. Also, you can change JES2 control blocks prior to the end of JES2 initialization.

- Job input processing
  You can modify how JES2 scans and interprets a job's JCL and JES2 control statements. Also, you can establish a job's affinity, execution node, and priority assignments before the job actually runs.

- Subsystem interface (SSI) processing
  You can control how JES2 performs SSI processing in the following areas: job selection and termination, subsystem data set OPEN, RESTART, allocation, CLOSE, unallocation, end-of-task, and end-of-memory.
JES2-to-operator communications
You can tailor how JES2 communicates with the operator and implement additional operator communications for various installation-specific conditions. Also, you can preprocess operator commands and alter, if necessary, subsequent processing.

Spool processing
You can alter how JES2 allocates spool space for jobs.

Output processing
You can selectively create your own unique print and punch separator pages for your installation output on a job, copy, or data set basis.

JES2-SMF processing
You can supply to SMF added information in SMF records.

RJE processing
You can implement additional security checks to control your RJE processing and gather statistics about signons and signoffs.

JES2 provides various strategic locations, called exit points, from where an installation-written exit routine can be invoked. JES2 can have up to 256 exits, each identified by a number from 0 to 255. JES2 code includes a number of IBM-defined exits, which have already been strategically placed in the code. For these IBM-defined exits you need only write your own exit routines and incorporate them via the EXIT(nnn) and LOAD(xxxxxx) initialization statements, where nnn is the exit point number and xxxxxx is the load module name.

If the IBM-defined exits are not sufficient, you can define your own exit points. However, exits established by you are modifications to JES2 code, and you must remember that you run a greater risk of disruption when installing a new version of JES2 code. The new JES2 code into which you have placed your exits may have significantly changed since the insertion of your exit point.

The IBM-defined exits can be classified into two categories:

- Not job-related exits:
  These are exits taken during functions not necessarily related to individual jobs (for example, JES2 initialization, JES2 termination, RJE, and JES2 command processing).

- Job-related exits:
  These exits are described in further detail in the following section.
3.15 JES2 input-related exits

Figure 3-15 JES2 input-related exits

JES2 input exits

Jobs that come in through the input phase go through the following exits:

- **Specific purpose exits** provide specific functions. These exits do not occur at predictable intervals during the life of a job. For that reason, they are not appropriate for general-purpose use. Examples of specific purpose exits are job output overflow (Exit 9) and spool partitioning exits (Exits 11 and 12).

- **General purpose exits** are usually considered when there is a user requirement to control installation standards, job resources, security, output processing, and other job-related functions.

There are two major considerations when selecting an exit to satisfy user requirements:

1. The environment of the exit
   This determines the addressable data areas, the facilities available when the exit is taken, and so forth.

2. The sequence of the exits
   Which exits precede and which exits follow each exit? What processing has preceded and followed the exit? It is very important to avoid some exit processing in order to avoid being overridden by another exit’s processing.

Often the use of more than one exit is required, and sometimes a combination of JES2 and other exits (such as Systems Management Facilities (SMF) exits) must be used. Table 3-2 on
page 145 and Table 3-3 on page 147 list the job-related exits in order to help you decide which exits to choose to control certain processes or functions during the life of a job.

Many installations use input service exits to control installation standards, tailor accounting information, and provide additional controls. When choosing an exit to act in this phase, it is important to consider all sources of jobs, especially if you want to select jobs from some sources to follow standards. For more details, refer to *JES2 Installations Exits*, SC28-1793

<td>Taken when a job’s data sets have been selected for printing or punching, prior to the check for the standard separator page.</td>
</tr>
<tr>
<td>2</td>
<td>JOB statement scan</td>
<td>The first exit taken for a job and before the statement is processed.</td>
</tr>
<tr>
<td>3</td>
<td>JOB statement accounting field scan</td>
<td>Taken after JOB statement has been processed. Normally used to replace or supplement JES2’s accounting field scanning routine (HASPRSCN), but also used as a post job card exit.</td>
</tr>
<tr>
<td>4</td>
<td>JCL and JES2 control statement scan</td>
<td>Taken for each JCL and JECL statement submitted but not for PROCLIB JCL statements.</td>
</tr>
<tr>
<td>6</td>
<td>Converter/Interpreter Text scan</td>
<td>A good exit for scanning JCL because of structured text and single record for each statement (no continuation).</td>
</tr>
<tr>
<td>7</td>
<td>$JCT Read/Write (JES2 environment)</td>
<td>Receives control when JES2 main task reads or writes the $JCT.</td>
</tr>
<tr>
<td>8</td>
<td>Control Block Read/Write (user or Subtask environment)</td>
<td>Taken from the user address space or a JES2 subtask each time a spool resident control block ($JCT, $IOT, $SWBIT, $OCR) is read from or written to spool.</td>
</tr>
<tr>
<td>15</td>
<td>Output Data Set/Copy Select</td>
<td>Taken once for each data set where the data set’s SPDDDB matches the selected Job Output Element ($JOE) and once for each copy of these data sets.</td>
</tr>
<tr>
<td>20</td>
<td>End of Job Input</td>
<td>Taken at the end of input processing and before $JCT is written. This is usually a good place to make final alterations to the job before conversion.</td>
</tr>
<tr>
<td>28</td>
<td>SSI Job Termination</td>
<td>Taken at the end of job execution before the $JCT is written to spool.</td>
</tr>
<tr>
<td>30</td>
<td>SSI Data Set Open/Restart</td>
<td>Taken for SYSIN, SYSOUT, or internal reader Open or Restart processing.</td>
</tr>
<tr>
<td>31</td>
<td>SSI Data set Allocation</td>
<td>Taken for SYSIN, SYSOUT, or internal reader Allocation processing. Uses: Fail an allocation. Affect how JES2 processes data set characteristics.</td>
</tr>
<tr>
<td>32</td>
<td>SSI Job Selection</td>
<td>Taken after all job selection processing is complete. Uses: Suppress job selection-related messages. Perform job-related processing such as allocation of resources and I/O for installation-defined control blocks.</td>
</tr>

</tr>
<tr>
<td>33</td>
<td>SSI Data Set Close</td>
<td>Taken for SYSIN, SYSOUT, or internal reader Close processing. Uses: Free resources obtained at OPEN.</td>
</tr>
<tr>
<td>34</td>
<td>SSI Data Set Unallocation - Early</td>
<td>Taken for SYSIN, SYSOUT, or internal reader early in allocate processing. Uses: Free resources obtained by Exit 30.</td>
</tr>
<tr>
<td>35</td>
<td>SSI End-of-Task</td>
<td>Taken at end of each task during job execution. Uses: Free task-related resources.</td>
</tr>
<tr>
<td>36</td>
<td>Pre-SAF</td>
<td>Taken just prior to JES2 call to SAF. Uses: Provide/change additional information to SAF. Eliminate call to SAF.</td>
</tr>
<tr>
<td>37</td>
<td>Post-SAF</td>
<td>Taken just after the return from the JES call to SAF. Uses: Change the result of SAF verification. Perform additional security authorization checking above what SAF provides.</td>
</tr>
<tr>
<td>40</td>
<td>Modifying SYSOUT</td>
<td>Taken during OUTPUT processing for each SYSOUT data set before JES2 gathers data sets with like attributes into a $JOE. Uses: Change the destination of a SYSOUT data set. Change the class of a SYSOUT data set to affect grouping.</td>
</tr>
<tr>
<td>44</td>
<td>Post Conversion (JES2 environment)</td>
<td>Taken after job conversion processing and before the $JCT and $JQE are checkpointed. Uses: Change fields in the $JQE and $JCT.</td>
</tr>
<tr>
<td>46</td>
<td>NJE Transmission</td>
<td>Taken for NJE header, trailer, and data set header during NJE job transmission. Uses: Remove/add/change installation-defined sections to an NJE data area before transmission.</td>
</tr>
<tr>
<td>47</td>
<td>NJE Reception</td>
<td>Taken for NJE header, trailer, and data set header during NJE job reception. Uses: Remove/change installation-defined sections that were previously added to an NJE data area.</td>
</tr>
<tr>
<td>48</td>
<td>Sysout unallocation - Late</td>
<td>More suitable then exit 34 when modifying SYSOUT characteristics or affecting SPIN processing.</td>
</tr>
<tr>
<td>49</td>
<td>Job Queue Work Select</td>
<td>Taken whenever JES2 has located a pre-execution job for a device. Uses: Provide an algorithm to accept or not accept a JES2-selected job. Control WLM initiator job selection.</td>
</tr>
</tbody>

<td>Receives control on the termination of each step or job. Uses: Decide whether the system is to continue the job (for step job). Decide whether SMF termination records are to be written to SMF data set.</td>
</tr>
<tr>
<td>IEFUJP</td>
<td>SMF Purge</td>
<td>Receives control when a job is ready to be purged from the system, after the job has terminated and all its sysouts have been written. Uses: Selectively decide whether the SMF job purge record (type 26) is to be written to the SMF data set.</td>
</tr>
</tbody>
</table>
3.16 JES2 exits in conversion phase

JES2 conversion exits

The conversion phase of JES2 processing is accomplished in two environments. First the Converter Processor Control Element ($PCE) is dispatched in the JES2 maintask environment to select a job from the input queue. Secondly, the Converter subtask, after being posted by the Converter maintask, calls the MVS Converter to do the actual conversion (JCL to C/I text). The reason for the subtask environment is that the conversion process requires the reading of the JCL data set from spool, reading JCL from PROCLIB, writing JCL images to spool, and the writing of C/I text to spool. These I/O operations cannot be accomplished in the maintask environment.

It's important to understand the difference in these two environments when considering exit usage. Exit 7 executes in the maintask environment, and Exit 6, and the SMF IEFUJV exit, execute in the subtask environment. If maintask functions are needed for a subtask exit, it may be necessary to use two exits, for example Exits 6 and 44 in conjunction, to provide a specific function.

Another important consideration is that there can be (and usually are) more than one converter processor (and subtask) and therefore, any exits taken in the subtask (Exits 6 and exit, IEFUJV) must be MVS reentrant. The scenario illustrated in Figure 3-16 is described by the conversion processing presented in Table 3-4.

Figure 3-16 JES2 exits in conversion phase
Table 3-4 Conversion Phase Processing

<table>
<thead>
<tr>
<th>Step</th>
<th>Processing</th>
<th>Exit used</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>A job is selected from the input queue, and the job's $JCT is read from spool. Exit 7 is invoked with a value of zero in general register zero (R0=0). The Daughter Task Element (DTE) is initialized and the Converter subtask is POSTed.</td>
<td>7</td>
</tr>
<tr>
<td>B</td>
<td>The JES2 conversion subtask locates the job's $PDBBs (JES2 Peripheral Data Definition Blocks) and Fake Opens the ACBs (Access Control Blocks) for internal text, job log, system messages, JCL, and JCL images data sets. The Converter subtask LOADs the MVS Converter, if the Converter has not already been loaded. Exit 8 is taken for reading the $IOTs from spool.</td>
<td>8</td>
</tr>
<tr>
<td>C</td>
<td>The Security Access Service ($SEAS) macro calls the Security Authorization Facility (SAF) to build the security environment in case the job stream contains MVS commands which if present, would be issued by the Converter using the Command SVC. The user ID associated with the command would be the user's, not JES2. As a result of the $SEAS call, Exits 36 and 37 are called.</td>
<td>36 37</td>
</tr>
<tr>
<td>D</td>
<td>For each JCL image, SMF exit IEFUJV (entry codes 0, 4, 8, and 64) is taken. This includes continuation statements. IEFUJV is called once more with an entry code of 16.</td>
<td>SMF exit IEFUJV</td>
</tr>
<tr>
<td>E</td>
<td>After the statement and all continuation statements have been converted into C/I text, the Converter exit, XTXTEXIT is called to provide spool data set names for SYSIN and SYSOUT JCL statements. If the statement represents a SYSIN data set, a $SEAS call is made to audit the creation.</td>
<td>XTXTEXIT</td>
</tr>
<tr>
<td>F</td>
<td>After the spool data set names have been generated (if SYSIN or SYSOUT), Exit 6 is invoked (R0=0) with the completed C/I text statement as input to the exit.</td>
<td>6</td>
</tr>
<tr>
<td>G</td>
<td>At the completion of conversion and after the Converter returns to the JES2 converter processor module, a $SEAS call is issued to delete the security environment. Exit 6 (R0=4) is taken again to allow final processing.</td>
<td>6</td>
</tr>
<tr>
<td>H</td>
<td>As a result of the $SEAS call, Exits 36 and 37 are called.</td>
<td>36 37</td>
</tr>
<tr>
<td>I</td>
<td>Exit 8 is taken to write the $IOTs. The JES2 converter processor module subtask POSTs its maintask and WAITs for the next job.</td>
<td>8</td>
</tr>
<tr>
<td>J</td>
<td>Exit 44 is taken to allow user modifications that require the maintask environment. Using the $DOGJQE macro you can access and optionally update fields in the JQE.</td>
<td>44</td>
</tr>
<tr>
<td>K</td>
<td>The JES2 converter processor module maintask checkpoints the $JCT, invokes Exit 7, and queues the $JQE to the execution job queue.</td>
<td>7</td>
</tr>
</tbody>
</table>

The conversion phase offers the only chance to have exit control over all of a job's JCL. Although SMF exit, IEFUJV is taken for each JCL and JCL continuation statement, JES2 Exit 6 offers some advantages.

First, the format of the C/I text is more structured. It is in parsed form and all major syntax errors have been removed. This has all been done by the converter before the exit gets control.
Another advantage of Exit 6 over IEFUJV is that once JCL statements have been converted into C/I text, there are no continuation statements. That is, the entire JCL statement, along with all continuation statements, are represented by a single C/I text statement.

A SAF security environment exists within the subtask and can be used with the RACF FACILITY class to control the specification of options within JCL. Exit 6 messages can be returned to the Converter to be issued by the Converter.
3.17 JES2 exits in execution phase

**Figure 3-17  JES2 exits in execution phase**

**JES2 execution exits**

This section attempts to merge those functions provided by a section of JES2 code in the JES2 Job Select/Termination module known as “Job Selection” and the pieces of MVS code known in the broad sense as the “Initiator.” The MVS Initiator consists of many modules which perform job selection, allocation, and initiator attach services (and others). JES2 Job Select also includes end-of-job functions.

For the purpose of this discussion, job selection is defined as the period, starting with the initiator's Subsystem Interface (SSI) call for job selection by class and ending with the JES2 message, $HASP373 JOB STARTED. Table 3-5 describes the processing that occurs during the Execution Phase, as depicted in Table 3-17.
### Table 3-5  Execution phase exits

<table>
<thead>
<tr>
<th>Step</th>
<th>Processing</th>
<th>Exit used</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>The MVS Job Selection module issues an SSI call specifying function code 5, which identifies the call to JES2 as a request to select a job by class. SSI calls with a function code of 5 are processed by the JES2 Job Select/Termination module. JBSELECT POSTs JES2 execution processing and WAITs for a job to be selected. If a JES2 initiator is selecting work, JES2 calls Exit 14 to allow the your installation to provide its own queue selection routine or to tailor the selection request. Exit 14 is not a job-related exit, that is, JES2 has not selected a job at this time. Exit 14 can select a job or it can tell JES2 to select a job. If a WLM initiator is selecting work, JES2 does not call Exit 14. After JES2 selects a job from the execution queue, it calls Exit 49, which can accept or reject the job. If Exit 49 rejects the job, JES2 searches for another job. JES2 does not call Exit 49 if Exit 14 selects a job. If JES2 execution processing finds a job that matches the Initiator’s defined job classes, it POSTs the waiting initiator and provides the job’s $JCT spool address in the $SJB. If a job has been found, control is given to the JBFOUND routine.</td>
<td>14</td>
</tr>
<tr>
<td>B</td>
<td>The JBFOUND routine reads the job’s JES2 $JCT using the spool address passed in the $SJB. Exit 8 is the first exit taken out of the user’s (or job’s) address space after a job is selected. This first entry to Exit 8 is taken after the job’s $JCT has been read. The job name and job-id are available as well as all other information in the $JCT. If later SMF exits for this job need addressability to the JES2 $JCT, store the JES2 $JCT address (as contained in Exit 8 parameter list) into the JCTUCOM field that later becomes the JMRUCOM.</td>
<td>8</td>
</tr>
<tr>
<td>C</td>
<td>Exit 8 is again taken to read the primary allocation $IOT. There also may be additional calls to Exit 8 to read secondary allocation $IOTs and/or $PDDB-only $IOTs based on the job’s JCL. Exit 8 is called for all spool control block reads and writes. JES2 allows installations to create extensions to the $JCT where job-related accounting data can be stored and transmitted through the network. Using the $JCTX macro extension service, you can add, expand, locate, and delete these extensions.</td>
<td>8</td>
</tr>
<tr>
<td>D</td>
<td>The JBFOUND routine calls the MVS SWA Create Control module to obtains storage for and initialize the Interpreter Entry List. The Interpreter Entry List contains information from JES2, such as user ID and security information, and is used for linking to the MVS Interpreter. Both JES2 and MVS have a data area named JCT. The two JCTs are not similar and one is not a copy, or partial copy, of the other. The Interpreter Entry List contains a pointer to the in-storage copy of the beginning of the $JCT JMR area which is used to create the CEPA/JMR. The MVS Interpreter Initialization routine calls the MVS Interpreter Router routine and after the internal text has been interpreted, the MVS Enqueue routine issues the call to SMF exit IEFUJV (entry code of 32). This is the first SMF exit for a job during the execution phase. The Scheduler Work Area (SWA) job and step tables have been created. The JMR pointer, called the CEPA in SMF documentation, is provided in the exit parameter list.</td>
<td>IEFUJV</td>
</tr>
<tr>
<td>Step</td>
<td>Processing</td>
<td>Exit used</td>
</tr>
<tr>
<td>------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>----------------</td>
</tr>
<tr>
<td>E</td>
<td>After the Interpreter returns control to the MVS SWA Create Control module, a RACROUTE REQUEST=VERIFY,ENV=CREATE is then issued to create the job’s security environment. The SAF Router exit is invoked if it exists and Message ICH70001I is issued by RACF identifying the user. If an error occurred during Job Select processing, for example a JCL error, then the job’s security environment is not created.</td>
<td>SAF Router exit</td>
</tr>
<tr>
<td>F</td>
<td>Exit 32 is called. The $JCT, all $IOTs, the JMR, and the ACEE have been created and are available. The JBSELECT routine then issues the $HASP373 JOB STARTED message.</td>
<td>32</td>
</tr>
<tr>
<td>G</td>
<td>Before job select processing is complete and control returns to the Initiator, JES2 checkpoints (writes to spool) the $JCT. Exit 8 is called.</td>
<td>8</td>
</tr>
<tr>
<td>H</td>
<td>Job initiation calls SMF exit, IEFUJI. MVS job initiation is a series of calls to step initiation based on the number of steps in a job.</td>
<td>IEFUJI</td>
</tr>
<tr>
<td>I</td>
<td>MVS step initiation consists of a call to SMF exit, IEFUSI, step allocation for those data sets and devices defined in the job’s JCL, and a call to the MVS Initiator Attach routine.</td>
<td>IEFUSI</td>
</tr>
<tr>
<td>J</td>
<td>Allocation of JCL defined SYSIN, SYSOUT, and internal readers initiates a call to Exit 31.</td>
<td>31</td>
</tr>
<tr>
<td>K/L</td>
<td>The MVS Initiator Attach routine attaches a subtask with an entry point of the program name specified on the EXEC JCL statement for the job step. The job step could dynamically allocate JES2 SYSIN, SYSOUT, or internal readers and therefore Exit 31 can be called.</td>
<td>31</td>
</tr>
<tr>
<td>M</td>
<td>The OPEN and CLOSE of JES2 data sets and internal readers call Exits 30 and 33.</td>
<td>30 33</td>
</tr>
<tr>
<td>N</td>
<td>Dynamic Unallocation of JES2 data sets and internal readers initiate a call to Exit 34. Exit 48 can be used in preference to Exit 34. Exit 34 may be too early to affect some fields in the $PDDB because unallocation processing takes place after Exit 34. Use Exit 48 when altering fields in the $PDDB, this exit can also be used to control Spin processing.</td>
<td>34 48</td>
</tr>
<tr>
<td>O</td>
<td>At End-of-Task (EOT) processing an SSI call is made to JES2 and Exit 35 is called.</td>
<td>35</td>
</tr>
<tr>
<td>P</td>
<td>Control is passed (return from Attach) to the MVS Initiator Attach routine and subsequently MVS Step Delete calls Step Unallocation which unallocates those data sets and devices defined in the job’s JCL on a step basis. Exit 34 is called for JCL defined SYSIN, SYSOUT, and internal readers. Exit 48 is also taken, as mentioned previously.</td>
<td>34 48</td>
</tr>
<tr>
<td>Q</td>
<td>The MVS Unallocation routine calls the MVS SMF Control routine which calls SMF exit IEFACTRT with entry codes 20 and 12. If additional job steps are to be processed, control is passed back to step 8. Otherwise, control is passed to Job Termination at step 17.</td>
<td>SMF exit IEFACTRT</td>
</tr>
<tr>
<td>R</td>
<td>Job Termination (actually this is Step Termination for the last step) again calls SMF exit IEFACTRT with entry codes 20 and 16. Control is then passed to MVS Step Delete where an SSI call (12) is made for Job Termination.</td>
<td>IEFACTRT</td>
</tr>
<tr>
<td>S</td>
<td>End-of-job processing calls Exit 28. This exit can clean up resources obtained over the life of job execution.</td>
<td>28</td>
</tr>
<tr>
<td>T</td>
<td>Spool control blocks are checkpointed. Exit 8 is taken for the $JCT write. The $JQE is placed on the OUTPUT queue to await output processing.</td>
<td>8</td>
</tr>
</tbody>
</table>
3.18 JES2 start procedure

How to start JES2
JES2 can be started after the z/OS system has been initialized. The z/OS system automatically starts JES2 if your installation provides this capability. Otherwise, you must issue the START command to invoke a JCL procedure in SYS1.PROCLIB that starts JES2.

JES2 initialization is performed after JES2 has been started. Initiators will not accept work (process jobs) until JES2 initialization is complete.

JES2 start procedure
To start the JES2 component, an installation must provide a subsystem cataloged JCL procedure (PROC). The PROC name can be a maximum of four characters. The PROC must be defined in the IEFSSNxx member of SYS1.PARMLIB.

The basic JCL procedure is shown in Figure 3-18. It contains an EXEC statement and five DD statements. The EXEC statement could specify the following parameters:

- **PGM=** Specify the name of the JES2 load module that resides in an authorized library.
- **TIME=** Specify 'NOLIMIT' or 1440 to prevent system ABEND code 322.
- **PARM=** Specify JES2 start options. It is suggested that you specify NOREQ for the start parameters. WARM is the default. Table 3-6 on page 161 lists the JES2 start options available.

```plaintext
//JES2     PROC M=JES2PARM
//IEFPROC  EXEC PGM=HASJES20,TIME=1440,
//HASPPARM DD DSN=SYS1.PARMLIB(MEMBER1)
//          DD DSN=SYS1.PARMLIB(COMMON)
//          DD DSN=SYS1.PARMLIB(NJEDEFS)
//          DD DSN=SYS1.PARMLIB(PRINTERS)
//PROC00   DD DISP=SHR,DSN=SYS1.PROCLIB
//PROC01   DD DISP=SHR,DSN=SYS1.PROCLIB
```

Figure 3-18 JES2 start procedure
It is recommended that you do not specify the REGION parameter to prevent any virtual storage limitations in the JES2 address space. The DD statement parameters specify as follows:

**PROC00**
Defines a default procedure library to be used for converting the JCL of batch jobs, time-sharing logons, and system tasks.

**PROCxx (01-99)**
Can be used to define other user-cataloged procedure libraries that are associated with job classes by the JOBCLASS initialization statement or by the /*JOBPARM JES2 control statement.

**HASPPARM**
Specifies the data set containing the initialization statements that will be used for JES2 initialization. With this statement, you can control all JES2 functions. The majority of them can be changed dynamically using JES2 commands.
3.19 HASPPARM using INCLUDE statement

INCLUDE initialization statement

With JES2 V1R2, the syntax of the INCLUDE initialization statement specifies a required data set name, and a volser and unit (required only if needed for allocation). The data set name can have a member name. The statements in the included data set are processed immediately. When the end of the included data set is reached, processing continues with the statement after the include of the original data set. Includes can be nested. There is loop detection to prevent a nesting loop.

The INCLUDE statement has the following considerations:

- DSNAME can include a member name.
- VOLSER and UNIT are optional (if data set is cataloged).
- Statements in the data sets are processed immediately.
- An INCLUDE data set can have INCLUDE statements.

The following example shows four members that make up the JES2 initialization definitions in the JES2 procedure. Using the INCLUDE statement, the JES2 procedure is simplified, as shown in Figure 3-19.
```plaintext
//JES2     PROC
//         EXEC PGM=HASJES20,...
//HASPPARM DD DSN=SYS1.PARMLIB(MEMBER1)
//         DD DSN=SYS1.PARMLIB(COMMON)
//         DD DSN=SYS1.PARMLIB(NJEDEFS)
//         DD DSN=SYS1.PARMLIB(PRINTERS)
```
3.20 Simplified procedure using default parmlib member

Enhancement to INCLUDE statement

Improvements to the INCLUDE initialization statement enable the reading of an additional member from the current data sets for the initialization statements. The new syntax added to the INCLUDE statement in JES2 V1R4 is as follows:

- INCLUDE MEMBER=member
  member_a should be in the current parmlib data set being processed.
- INCLUDE PARMLIB_MEMBER=member
  member_b should be in the default logical parmlib.

Note: The new keywords MEMBER and PARMLIB_MEMBER are mutually exclusive with the keywords DSNAME or VOLSER or UNIT.

Default parmlib member

This JES2 V1R4 support allows for a default PARMLIB member. This member is used only if there is no HASPPARM DD and the operator does not use a HASPPARM= start option. The default is HASJES2 where JES2 is the actual subsystem name. The default member comes from the logical PARMLIB concatenation.

There is also the ability to specify the "default" member as a start option, (MEMBER=). If MEMBER= is specified, it will be used. HASPPARM= and MEMBER= are mutually exclusive and can be specified as follows:
MEMBER=
If specified by the operator as a start option, then use that member as the
default PARMLIB.

HASPPARM=
If specified by the operator as a start option, then use that DD name for
the PARMLIB.

HASPPARM DD
If this DD exists in the JES2 procedure, then use that DD name as the
PARMLIB.

**Note:** If none of the above are specified, then use HASJES2 as the default PARMLIB con-
catenation.

If there is any problems with any of these, message HASP450 is issued and then the operator
can respond if JES2 should continue, just as is done previously if the OPEN of the DD for
PARMLIB fails. If the operator replies 'Y', JES2 initialization continues and console mode is
entered, which again is the same as previously.

**PARMLIB search order**
Following is the search order to determine which PARMLIB to use:

1. If HASPPARM=ddname parameter is specified, use that DD.
2. If MEMBER=PARMLIB_MEMBER= parameter is specified, use that member from logical
   PARMLIB.
3. If neither is specified, try to open DD with ddname of HASPPARM.
4. If no HASPPARM DD is found, use HASJES2 member from the logical parmlib, which is the
default PARMLIB concatenation. This is HASJES2 in the examples.

**Using default PARMLIB**
With the new enhancements to the INCLUDE processing, it is now possible to remove the
HASPPARM DD from the JES2 procedure, as shown in Figure 3-20. In this example, all the
members must be in the logical PARMLIB concatenation and they are in SYS1.PARMLIB.

The HASJES2 member contains an INCLUDE statement that points to PARMLIB member
JES2M1, as the value of &SYSJCLONE is M1.
3.21 JES2 start parameters

JES2 uses start options to determine how it will perform the current initialization. You can specify start options in either of two ways:

- As parameters on the EXEC statement in the JES2 procedure
- As options specified at the console

If you do not specify the options on the EXEC statement, JES2 requests them from the operator by issuing the $HASP426 (SPECIFY OPTIONS) message.

The operator then enters the options using the standard reply format as described in z/OS JES2 Commands. The operator can enter options in upper or lower case; they must be separated by commas. If the operator enters conflicting options (for example, WARM,COLD), the last option specified is the one JES2 uses.

If the options are specified on the EXEC statement, JES2 suppresses the $HASP426 (SPECIFY OPTIONS) message and completes initialization without operator intervention unless CONSOLE control statements have been added to the JES2 initialization data set or an initialization statement is in error.

If you let JES2 prompt for the options, JES2 issues message $HASP426:

*id $HASP426 SPECIFY OPTIONS - jesname

**Figure 3-21 JES2 start parameters**

- COLD/WARM
- CKPT1/CKPT2
- NOREQ/REQ
- NOLIST/LIST
- NOLOG/LOG
- FORMAT/NOFMT
- HASPPARM=ddname
- SPOOL=VALIDATE/NOVALIDATE

**JES2 start options**

- CONSOLE
- REC ONFIG
- NONE / U / N
You should respond using the z/OS `REPLY` command to specify the JES2 options determined by your installation procedures.

```
REPLY id, options
```

Table 3-6 explains the JES2 start options.

If you respond to message $HASP426 with the `$PJES2` command, JES2 will terminate.

**Note:** If you specify the `NOREQ` option, JES2 will automatically start processing following initialization. Otherwise, you must enter the `$S` command in response to the `$HASP400 ENTER REQUESTS` message to start JES2 processing.

### Table 3-6  JES2 start parameters

<table>
<thead>
<tr>
<th>Option</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>FORMAT NOFMT</td>
<td>FORMATT specifies that JES2 is to format all existing spool volumes. If you add unformatted spool volumes, JES2 automatically formats them whether FORMAT is specified or not. With FORMAT, JES2 automatically performs a cold start. Default: NOFMT specifies that JES2 is not to format existing spool volumes unless JES2 determines that formatting is required.</td>
</tr>
<tr>
<td>COLD WARM</td>
<td>COLD specifies that JES2 is to be cold-started. All jobs in the system will be purged and all job data on the spool volumes will be scratched. Default: WARM specifies that JES2 is to continue processing jobs from where they were stopped. If the FORMAT option was also coded, then JES2 will ignore the WARM specification and perform a cold start.</td>
</tr>
<tr>
<td>SPOOL = VALIDATE NOVALIDATE</td>
<td>VALIDATE specifies that the track group map is validated on a JES2 all-member warm start. Default: SPOOL=NOVALIDATE specifies that the track group map is not validated when JES2 restarts.</td>
</tr>
<tr>
<td>NOREQ REQ</td>
<td>NOREQ specifies that the $HASP400 (ENTER REQUESTS) message is to be suppressed and JES2 is to automatically start processing when initialization is complete. Default: REQ specifies that the $HASP400 (ENTER REQUESTS) message is to be written at the console. This message allows you to start JES2 processing with the $S command.</td>
</tr>
<tr>
<td>NOLIST LIST</td>
<td>NOLIST specifies that JES2 is not to print the contents of the initialization data set or any error flags that occur during initialization. If you specify NOLIST, JES2 ignores any LIST control statements in the initialization data set. z/OS JES2 Initialization and Tuning Reference presents an example of an initialization data set listing produced by using the list option. Default: LIST specifies that JES2 is to print all the statements in the initialization data set and any error flags that occur during initialization. (JES2 prints these statements if a printer is defined for that purpose when JES2 is started.) LIST will not print any statements that follow a NOLIST control statement in the initialization data set.</td>
</tr>
<tr>
<td>NOLOG LOG</td>
<td>NOLOG specifies that JES2 is not to copy initialization statements or initialization errors to the HARDCPY console. If you specify NOLOG, JES2 ignores LOG control statements in the initialization data set. Default: LOG specifies that JES2 is to honor any LOG statements in the initialization data set.</td>
</tr>
</tbody>
</table>
You can now start JES2 with the new start option of reading the initialization stream from the default PARMLIB specification, as follows:

- S JES2,PARM=('MEMBER=member')
- S JES2,PARM=('PARMLIB_MEMBER=member')

The operator should reply to the $HASP467 message as follows:

r xx,MEMBER=member

where member is the member of logical parmlib in each of the above specifications.

The following conditions should be considered:

- HASPPARM=ddname and MEMBER= are mutually exclusive.
If neither HASPPARM= nor MEMBER= is specified, then it will process from the default HASjesx member of logical parmlib (where jesx is the JES2 subsystem name).

IBM does not ship a default parmlib member.

Starting JES2 without a JES2 PROC
In an emergency, you can start JES2 without a JES2 procedure because of the elimination of the need to specify the HASPPARM data set and the PROCLIB data sets, a change that was introduced in JES2 V1R2. Start JES2 as follows:

S IEESYSAS, PROG=HASJES20, JOBNAME=JES2

This start command assumes that HASJES20 is in the LINKLIST (no STEPLIB). During JES2 initialization when the OPEN of HASPPARM fails, the logical parmlib member HASJES2 will be used. If HASJES2 is not found, message $HASP469 is issued.

S IEESYSAS, PROG=HASJES20, JOBNAME=JES2, PARM='MEMBER=MEMBER2'

This start command uses the logical parmlib member MEMBER2 and no OPEN of the HASPPARM DD is attempted. This option is new with JES2 V1R4 because of the new MEMBER= capabilities. If MEMBER2 is not found, message $HASP469 is issued.
3.22 Restarting JES2

- **Cold start**
  - All job data in spool is lost

- **Warm start**
  - All-member warm start
  - Single-member warm start
  - Quick start
  - Hot start

---

**Restarting JES2 with cold start option**

Very few definitions, or redefinitions, of some JES2 facilities and resources require that the JES2 system be totally shut down. JES2 must be restarted with a cold start to allow all component systems to be aware of the changed facilities and resources. The time to restart JES2 in this manner is based on the work in the system and, if not scheduled, causes a disruption in data processing services. All job data previously on the spool volumes is lost with cold start. You can avoid data loss by scheduling a spool offload of the JES2 queues. In a MAS configuration, no other member can be active during a cold start. Use of the FORMAT option causes a cold start.

An IPL must precede a JES2 cold start, unless JES2 was stopped with a $P JES2 operator command.

**Warm start**

During a warm-start initialization, JES2 reads through its job queues and handles each job according to its status:

- Jobs in input readers are lost and must be reentered.
- Jobs in output (print/punch) are requeued and later restarted. The checkpoint for jobs on the 3800 printer points to the end of the page being stacked at the time of the checkpoint. Jobs that were sent to the 3800 printer but that did not reach the stacker are reprinted from the checkpoint. If no checkpoint exists, then it is reprinted from the beginning.
Jobs in execution are either requeued for execution processing or are queued for output processing.

All other jobs remain on their current queues.

There are four ways in which a warm start can be performed in a multi-access spool configuration, as follows:

1. All-member warm start

An all-member warm start is performed if a warm start is specified by the operator and JES2 determines that no other members of the configuration are active or there is only one member in the configuration. All in-process work in the MAS will be recovered. After an all-member warm start, other members entering the configuration for the first time will perform a quick start.

2. Single-member warm start

This is performed when WARM is specified and others members of the configuration are active. The warm-starting member joins the active configuration and recovers only work in process on that member when it failed or was stopped.

3. Quick start

This is performed when you specified a warm start and JES2 determined that the job queue and job output table do not need to be updated. In this case, the member being started is not the first member being started in the MAS. This occurs:

- After $P JES2 has been issued to quiesce the member. Because all work is quiesced, there is no need to update the job queue or job output table before restarting.

- After an all-member warm start has been performed and no work is waiting to be processed; therefore, the job and output queues are empty.

- When a $E MEM command was entered at a processor within the MAS configuration other than the member being started.

4. Hot start

This is a warm start of an abnormally terminated JES2 member without an intervening IPL. When it happens, all address spaces continue to execute as if JES2 had never terminated. JES 2 validates (and rebuilds, when necessary) the job and output queues and the job queue index. Damaged or corrupted job output elements (JOEs) and job queue elements (JQEs) are placed on the rebuild queue.
3.23 Stopping JES2

- $P$ command to stop all JES2 processing
- Log off all TSO/E users
- $\$HASP099$
- Stop all started tasks
- $\$P$ JES2
  - $\$P$ JES2,QUICK (poly-JES environment)
  - $\$P$ JES2,ABEND
  - $\$P$ JES2 ABEND,FORCE
- HALT EOD

Figure 3-23  Stopping JES2

Stopping JES2

There are instances when JES2 must be stopped and restarted either by a warm or cold start. For example, redefining the number of systems in a network job environment requires a warm start. You can stop and restart JES2 in a system at any time by using operator commands. This allows you to:

- Quiesce job processing in preparation for an orderly system shutdown.
- Restart JES2 to perform an initialization with different initialization parameter specifications.

You can dynamically change JES2 initialization statements by using the $\$T$ operator for most parameters. Before stopping JES2 for the purpose of changing initialization statement parameters, refer to z/OS JES2 Initialization and Tuning Reference, SA22-7533-03.

To stop JES2, do the following:

1. Issue the $\$P$ command to stop all JES2 processing. System initiators, printers, punches, job transmitters, and SYSOUT transmitters will not accept any new work and will become inactive after completing their current activity. However, new jobs will be accepted through input devices. When all TSO users log off, and all JES2 started tasks, logical initiators, printers, and punches complete their current activities and become inactive, JES2 notifies you with the following message:

   $\$HASP099$ ALL AVAILABLE FUNCTIONS COMPLETE

2. Stop all started tasks.
3. Enter the $P JES2 command to withdraw JES2 from the system. If any jobs are being processed or any devices are active, the $P JES2 command is processed as a $P command and drains JES2 work from the system.

   If it is not possible or reasonable to drain the JES2 member (for example, due to large numbers of lines, jobs, and remote; or, if you plan to restart JES2 using a hot start) you can specify:

   $P JES2,ABEND

   The ABEND parameter forces JES2 termination regardless of any JES2 or system activity. If the checkpoint resides on a Coupling Facility structure and the member is processing a write request, JES2 issues the $HASP552 message and delays the $P command until the checkpoint write has completed.

   If the $P JES2,ABEND command does not successfully terminate JES2, you can also specify the FORCE parameter. The $PJES2,ABEND,FORCE command results in a call to the recovery termination manager (RTM) to terminate the JES2 address space. Because the FORCE parameter can cause unpredictable results, always attempt to enter the $P JES2,ABEND command first.

   To withdraw JES2 from a system involved in cross-system activity, you can issue the $P JES2,QUICK command. Cross-system activity occurs when a user on one JES2 subsystem requests a cross-system function from another JES2 subsystem within the same poly-JES2 environment. This option deletes the control blocks for the request submitted by the user who requested cross-system function. Before using the QUICK keyword on the $P JES2 command, you should send a message to the user asking them to end their cross-system activity.

4. Issue the HALT E00 command. It ensures that important statistics and data records in storage are not permanently lost.
3.24 JES2 operations

No large data processing system or subsystem can continuously operate independently of system programmer or operator intervention. To help you maintain your overall work environment, JES2 provides a set of commands that permits you to control most of the JES2 functions and devices under its control.

As your JES2 complex becomes more sophisticated, you might connect your system to others to form a network of systems. You can use operator commands to control the lines that connect the separate systems, as well as to define the separate systems to yours. This is typically a very dynamic environment since different systems are added or deleted from the network due to maintenance, hardware reconfiguration requirements, workload balancing, or the need to access a database at a different location. JES2 commands permit you to alter most of your original network definition, as required. Almost all JES2 initialization statements can be changed dynamically by JES2 operator commands.

Operator commands can be used to:
- Display status information and device definition
- Start, stop, and halt devices under JES2's control
- Assign units to local printers, punches, card readers, and lines, or reassign units to these devices
Modify processing, such as: output definition, the dynamic alteration of the checkpoint definition, enabling installation-defined exits, offload devices, printer and punch characteristics, and job characteristics

- Add function and functional subsystems
- Delete function, network systems, exits, and diagnostic traces

Your installation can require that only certain operators can issue certain JES2 commands and/or restrict commands coming in from RJE workstations, NJE nodes, or any other device. You can use RACF and customization techniques to limit the degree of control an individual or group can have over JES2 resources.

All JES2 commands are entered using standard z/OS command interfaces such as a z/OS console, or within the JES2 initialization data set. As the default, JES2 prefixes its commands and messages with a dollar sign ($). For commands, the prefix character defines the scope of the command as being JES2 only; for messages, the prefix character is informational in that it designates that the message was issued by the JES2 component. You can change this symbol through the CONDEF initialization statement.
3.25 Controlling the JES2 environment

The following commands are useful to control the JES2 environment:

- **Start JES2 processing, $S**
  To start system activity.

- **Stop JES2 processing, $P**
  To stop all system initiators, printers, punches, job transmitters, and SYSOUT transmitters after they complete their current activity.

- **Withdraw JES2 from the system, $P JES2**
  To withdraw JES2 from the system to which the entering console is attached.

- **Monitor local buffers, $T BUFDEF**
  To specify the percentage of local buffers use at which JES2 alerts the operator of a local buffer shortage. Local buffers can reside below 16 megabytes of virtual storage or above 16 megabytes of virtual storage.

- **Monitor SMF buffers, $T SMFDEF**
  To set the SMF buffer warning level.
3.26 Controlling a MAS environment

The following commands are useful to control your multi-access spool (MAS) environment:

- **Display characteristics of the MAS, $D MASDEF**
  
  To display multi-access spool definition and tuning parameters.

- **Display the status of MAS members, $D MEMBER**
  
  The information displayed for each member includes the member name and any of the following information:
  - The date and time the member was started.
  - The member that is restarting this member's work.
  - The status of the member.
  - The name of the MVS system image of the member.
  - The time the member last accessed the checkpoint.
  - The version of JES2 running on the member.

  This command has parameters you can use as a filtering technique to limit the type of information to search, or the amount of information to display.

- **Control the MAS environment, $T MASDEF**
  
  To specify multi-access spool definition and tuning parameters.

- **Display the checkpoint definition, $D CKPTDEF**
  
  This command has parameters you can use as a filtering technique to limit the type of information to search, or the amount of information to display.

- **Control the checkpoint definition, $T CKPTDEF**
  
  - To modify the checkpoint definition
  - To initiate a checkpoint reconfiguration dialog with JES2
3.27 Controlling JES2 spooling

Figure 3-27 Controlling JES2 spooling

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$D SPOOL</td>
<td>Display spool volume usage.</td>
</tr>
<tr>
<td>$S SPOOL</td>
<td>Start a spool volume.</td>
</tr>
<tr>
<td>$T SPOOLDEF</td>
<td>Control the JES2 spooling environment.</td>
</tr>
<tr>
<td>$P SPOOL</td>
<td>Drain a spool volume.</td>
</tr>
<tr>
<td>$Z SPOOL</td>
<td>Halt a spool volume.</td>
</tr>
</tbody>
</table>

Controlling the JES2 spool

The following commands are useful to control the JES2 spool:

- **Display spool volume usage, $D SPOOL**
  
  To display the status and percent utilization of a specified spool volume or all spool volumes

- **Start a spool volume, $S SPOOL**
  
  To add or reactivate a spool volume to the spool configuration

- **Control the JES2 spooling environment, $T SPOOLDEF**
  
  To specify the JES2 spooling environment characteristics

- **Drain a spool volume, $P SPOOL**
  
  To drain and delete an entire spool volume by processing all work on the volume and preventing any available space on the volume from being allocated

- **Halt a spool volume, $Z SPOOL**
  
  To deallocate a spool volume after active work completes its current phase of processing (executing, printing, punching)
3.28 Controlling JES2 jobs

The following commands are useful to control JES2 jobs:

- Release specified jobs, `$A Job`
- Cancel a job, `$C Job`
- Cancel output groups, `$CO Job`
- Display information about a specified job, `$D Job`
- Hold a specified job, `$H Job`
- List job output information, `$L Job`
- Release or cancel held output groups, `$O Job`
- Purge a job, `$P Job`
- Purge an output job, `$PO Job`
- Change a job’s class, scheduling priority, or member affinity, `$T Job`
- Set output characteristics, `$T O`

Figure 3-28  Controlling JES2 jobs
3.29 Controlling JES2 printers

The following commands are useful to control JES2 printers:

- **Display printers, $D PRT**
  
  To display printer work selection and processing characteristics. This command has parameters you can use as a filtering technique to limit the type of information to search, or the amount of information to display.

- **Restart printer activity, $E PRTnnnn**
  
  To stop the printing of the current output group and requeue the output according to its job priority for later processing.

- **Stop a printer, $P PRTnnnn**
  
  To stop a printer after it completes processing the current output group and then free the associated system resources.

- **Start a printer, $S PRTnnnn**
  
  To start printer activity. The $HASP190 message asks whether the requested setup has been completed for the specified device. Either verify that the setup is complete or issue the $T PRTnnnn command to override specific setup specifications. Then reissue the $S command to physically start the printer.

- **Halt printer activity, $Z PRTnnnn**
  
  To temporarily halt local or remote printer activity.
**JES2 diagnosis communication mechanisms**

The following diagnostic tools are available for detecting and diagnosing problems occurring in the JES2 environment:

- **Messages**
  JES2 provides a set of messages to alert the JES2 operator and system programmer of processing errors.

- **Traces**
  Optionally, your installation can use the JES2 tracing facility, a function that records events associated with specific functions, such as each time JES2 is initialized or terminated or each time an exit routine is taken.

- **IPCS**
  JES2 exploits the interactive problem control system (IPCS) facility to allow you to view the formatted contents of JES2 control blocks and dumps of system data necessary when diagnosing and recovering from processing errors.
3.30 JES3 processing

With the z/OS MVS JES3 system, resource management and workflow management are shared between MVS and its JES3 component. Generally speaking, JES3 does resource management and workflow management before and after job execution, while MVS does resource and workflow management during job execution.

JES3 considers job priorities, device and processor alternatives, and installation-specified preferences in preparing jobs for processing job output. The features of the JES3 design include:

- Single-system image
- Workload balancing
- Availability
- Control flexibility
- Physical planning flexibility

Figure 3-30 shows the JES3 topics discussed in this section.
3.31 JES3 configuration

**Figure 3-31  JES3 configuration**

**JES3 configuration**

JES3 can run on a single processor, or on multiple processors, up to thirty-two processors in a sysplex. A *sysplex* is a set of MVS systems communicating and cooperating with each other through certain multisystem hardware components and software services to process customer workloads.

The hardware components used for connecting the systems are:

- A sysplex timer to synchronize the TOD clocks of the processors of a sysplex (not required if a sysplex is located on only one processor).
- Channel-to-channel connections to connect the members of a sysplex to house a coupling data set.

In a sysplex, your installation must designate one processor as the focal point for the entry and distribution of jobs and for the control of resources needed by the jobs. That processor, called the *global processor*, distributes work to the processors, called local processors.

It is from the global processor that JES3 manages jobs and resources for the entire complex, matching jobs with available resources. JES3 manages processors, I/O devices, volumes, and data. To avoid delays that result when these resources are not available, JES3 ensures that they are available before selecting the job for processing.

JES3 keeps track of I/O resources, and manages workflow in conjunction with the workload management component of MVS by scheduling jobs for processing on the processors where
the jobs can run most efficiently. At the same time, JES3 maintains data integrity. JES3 will not schedule two jobs to run simultaneously anywhere in the complex if they are going to update the same data.

JES3 may be operated from any console that is attached to any system in the sysplex. From any console, an operator can direct a command to any system and receive the response to that command. In addition, any console can be set up to receive messages from all systems, or a subset of the systems in the sysplex. Thus, there is no need to station operators at consoles attached to each processor in the sysplex.

If you want to share input/output (I/O) devices among processors, JES3 manages the sharing. Operators do not have to manually switch devices to keep up with changing processor needs for the devices.

The JES3 architecture of a global processor, centralized resource and workflow management, and centralized operator control is meant to convey a single-system image, rather than one of separate and independently-operated computers.

JES3 runs in the following environments:
- Single-processor environment
- Multiprocessor environment
- Remote job processing environment
- JES3 networking environment
- APPC environment

A JES3 complex can involve any combination of these environments.
3.32 JES3 complex

**JES3 complex**

z/OS uses JES3 to control the input, processing, and output of jobs. JES3 services the job processing requirements of from 1 to 32 physically connected z/OS processors called *mains*. Viewed as a whole, the 1- to 32-main environment serviced by JES3 is called a *complex*.

JES3 has its own private address space in each of the mains in the complex. One main, the JES3 global main, is in control of the entire complex. There must be a *global main*; if there is only one main in the complex, that main is the global. In a complex with more than one main, the other mains in which JES3 resides are called *local mains*. There can be as many as 31 local mains.

JES3 is designed so that if the global fails, any properly-configured local within the complex can assume the function of the global through a process called dynamic system interchange (DSI). Figure 3-32 illustrates the basic structure of a JES3 complex.

There can be as many as 31 local mains.

JES3 is designed so that if the global fails, any properly-configured local within the complex can assume the function of the global through a process called dynamic system interchange (DSI). Figure 3-32 illustrates the basic structure of a JES3 complex.
3.33 MVS and JES3 environment

- **Primary subsystem** - JES3
  - System input and output - (JES3 Global)
  - Manage jobs and spool - (JES3 Global)

- **Functional subsystems** - FSS
  - Offload function to locals and global address space
    - Converter/Interpreter and printers
  - JES3 global controls
    - FSS start and stop
    - Selection of work
    - Operator communication

**Figure 3-33 MVS subsystems in JES3 environment**

**JES3 as a primary subsystem**
As the primary subsystem, the global JES3 plays as important role, and the following functions provided by JES3 indicate why communication is needed between MVS and JES3. The global JES3:
- Introduces all jobs into the system, no matter what the source.
- Handles scheduling of conversion and interpretation of JCL.
- Performs pre-execution setup of devices.
- Schedules MVS jobs to all main processors.
- Maintains awareness of all jobs in execution.
- Handles the scheduling of all SYSOUT data sets.
- Manages the allocation and deallocation of space on the shared-spool devices.

When carrying out some of these responsibilities, global JES3 needs the assistance of local JES3. This is true during the scheduling of work on the local processor.

**Functional subsystem**
JES3 allows certain functions to operate outside the JES3 address space. JES3 does this using:
- The functional subsystem address space (FSS)
The functional subsystem interface (FSI)

The functional subsystem application (FSA)

The JES3 FSS that deals with output services is one type of FSS. This particular FSS address space may be created automatically or established by a CALL command for a printer device which is capable of running under the control of an FSS address space. The operator CALL command designates a printer as a “hot writer,” while a writer invoked automatically when output is queued is called a “dynamic writer.”

Another FSS deals with converter/interpreter services similar to those that occur in the JES3 global.
3.34 JES3 global

- Global processor manages jobs and resources
  - For the entire complex
  - Matches jobs with available resources
- JES3 global manages
  - Processors - I/O devices - Volumes - Data sets
- When resources are not available
  - JES3 ensures that they are before selecting the job for processing to an initiator
- Operations aid
  - Operator commands
  - Diagnostic tools

Figure 3-34  JES3 global

JES3 global processor

It is from the global processor that JES3 manages jobs and resources for the entire complex, matching jobs with available resources. JES3 manages processors, I/O devices, volumes, and data. To avoid delays that result when these resources are not available, JES3 ensures that they are available before selecting the job for processing.

JES3 provides installation benefits from the distribution of work among processors as a workflow manager. The entry of all jobs through a central point means that control of the actions needed to prepare jobs for execution can be centralized. The distribution and duplication of job management function becomes unnecessary, and an awareness of the status of all jobs entering or leaving the system can be easily maintained. This awareness is particularly useful in recovery situations, where the scope of recovery is largely a function of the quality of the tracking performed prior to the failure.

Resource manager

Another benefit is resource management. All jobs, all input required for the jobs, and all output produced by the jobs enters or leaves the system at a single point. This single point, JES3, can coordinate the subsystem, the allocation of devices, volumes, and data sets. Centralized resource control expands the opportunity for full resource utilization. If you are using the storage management subsystem (SMS), you can allow SMS to coordinate the allocation of permanently resident catalog volumes and cataloged data sets. When SMS is activated, JES3 will not manage devices and volumes for SMS-managed data sets.
JES3 keeps track of I/O resources, and manages workflow in conjunction with the workload management component of MVS by scheduling jobs for processing on the processors where the jobs can run most efficiently. At the same time, JES3 maintains data integrity. JES3 will not schedule two jobs to run simultaneously anywhere in the complex if they are going to use the same serially reuseable resources. If you want to share input/output (I/O) devices among processors, JES3 manages the sharing. Operators do not have to manually control the online/offline status of devices to keep up with changing processor needs for the devices.

**Operations aid**

Operator control also benefits from improved resource utilization and centralized job management. With all system resources known to JES3 and with one job management mechanism, it is relatively simple to provide control over the entire system. And yet, the need for operator control can be minimized because JES3 is aware of job mix and resource availability and can coordinate them with less need for operator intervention and decision-making.

Operators have special JES3 commands. Some commands activate programs to handle I/O devices, while others obtain or change the status of jobs being processed. With multiple processing-unit systems, JES3 operators have less to do than for an equal number of individual systems, because they can control the entire complex from a central point, and because JES3 decides where and when jobs will be processed.

For diagnostic purposes, JES3 provides traces and dumps. Traces are copies of data made during normal processing to help monitor activity in the system, and dumps are copies of data made at times of failure.
3.35 JES3 sysplex components

- **Sysplex** - 1 to 32 coupled systems
  - Using hardware and software elements
- **XCF** - Cross-system coupling facility
  - Provides communication services for a sysplex
- **CTC** - Channel to channel adapter
  - Provides direct connection between MVS systems
- **GRS** - Global resource serialization
  - Used to serialize resources - Uses XCF

**JES3 sysplex components**

The sysplex components and terminology are as follows:

- **Sysplex**
  - Up to 32 systems or MVS images may be defined in a sysplex coupled together by hardware and software elements.

- **XCF**
  - The cross-system coupling facility (XCF) is the operating system component that controls members and groups, provides inter-member communications (exchange data, programs, and so on), and monitoring services for members.

- **CTC**
  - A CTC is used for channel-to-channel connectivity. It is a form of direct connection between processors or between channels of the same processor. In the context of this document, this type of connection refers to an ESCON® channel operating in CTC mode. CTC links may be used when a sysplex is made up of two or more systems.

- **GRS**
  - Whenever one or more systems in a GRS complex are not in a sysplex, GRS uses its own dedicated CTCs to communicate between systems not in the sysplex, and uses XCF services between systems in the sysplex.
JES3 multisystem sysplex

With multiple MVS images in multiple CPCs, PLEXCFG=MULTISYSTEM is the XCF mode required. A Sysplex Timer® is required, as shown in the Figure 3-36. The two JES3 systems communicate using XCF, and the signalling services can be through either CTCs or the coupling facility.

Multiprocessing is a way of doing work with two or more connected processors. Some of the advantages of running JES3 in this environment are:

- Elimination of much of the overhead of scheduling work for and operating separate processors
- Sharing devices by processors, which means that the devices can be used more efficiently
- Movement of work to other processors, should one processor become overworked, need maintenance, or need to be removed from the complex for any reason

The global processor and the local processors communicate using the MVS cross-system coupling facility (XCF). JES3 devices (the devices from which JES3 reads jobs, and on which JES3 stores jobs awaiting processing, stores job output, and writes job output) are connected to the global processor. Some JES3 devices that write job output can also be connected to the local processors.
The global processor runs most of JES3, for it is from the global processor that JES3 allocates resources to jobs and sends jobs to local processors for processing. In addition, JES3 can also pass jobs to MVS in the global processor for processing.

Each local processor has a complete MVS system and JES3 routines for spooling and for communication with the global processor. When MVS in a local processor needs a job, JES3 in that local processor sends the job request to JES3 in the global processor via XCF signalling. JES3 in the global processor returns identifying information about a job, and JES3 in the local processor uses that information to retrieve the job from the spool device.

If a problem arises on the global processor while JES3 is running, you can transfer global functions to a local processor. This transfer is called dynamic system interchange (DSI). The processor you choose must be capable of assuming the same workload as the previous global.
### 3.37 JES3 global functions

#### JES3 Global functions

- **Workflow manager**
  - Schedule jobs
  - Manage job queue
  - System coupler

- **Resource manager**
  - Processors - Devices - Volumes - Data sets

- **Operations aid**
  - Operator commands
  - Diagnostic tools

---

**JES3 global functions**

The JES3 global controls all work in a JES3 complex, as follows:

- **Workflow manager**: JES3 provides installation benefits from the distribution of work among processors as a workflow manager. The entry of all jobs through a central point means that control of the actions needed to prepare jobs for execution can be centralized. The distribution and publication of job management functions becomes unnecessary, and an awareness of the status of all jobs entering or leaving the system can be easily maintained.

- **Resource manager**: Another benefit is resource management. All jobs, all input required for the jobs, and all output produced by the jobs enters or leaves the system at a single point. This single point, JES3, can coordinate the subsystem, the allocation of devices, volumes, and data sets. Centralized resource control expands the opportunity for full resource utilization. If you are using the storage management subsystem (SMS), you can allow SMS to coordinate the allocation of permanently resident catalog volumes and cataloged data sets. When SMS is activated, JES3 will not manage units and volumes for SMS-managed data sets.

- **Operations aid**: Operator control also benefits from improved resource utilization and centralized job management. With all system resources known to JES3 and with one job management mechanism, it is relatively simple to provide control over the entire system. And yet, the need for operator control can be minimized because JES3 is aware of job mix and resource availability and can coordinate them with little need for operator intervention and decision-making.
3.38 JES3 terminology

JES3 naming conventions

Module names: IAT ff xx
- FF: functional area
- XX: function performed

Module examples
- IATISDV - IATOSDR - IATSICA
- IATISDR - IATOSSC - IATSI34

Coding macros - IATX...
Data macros - IATY...
JES3 nucleus - IATNUC

JES3 terminology and naming conventions

Most JES3 module names are seven characters long and begin with the characters IAT. The fourth and fifth characters are a mnemonic that represents a specific function. The sixth and seventh characters indicate a service preformed by that module within the function. For example IATISDV:
- IAT signifies that this is a JES3 module.
- IS signifies that this is an input service module.
- DV signifies that this is the device driver module.

The mnemonic in the fourth and fifth character indicates any of the following module functions:
- AB abnormal termination
- BD MVS/Bulk Data Transfer
- CN console services
- DC dependent job control
- DJ dump job
- DL deadline scheduling
- DM spool data management
- DS dynamic system interchange
- DY dynamic allocation fastpath
- FC/FP functional subsystem interface
- FS failsoft
Chapter 3. Job management

GR  general routines
GS  general service
II  converter/interpreter service
IN  initialization
IP  interactive problem control system
IQ™ operator inquiry commands
IS  input service
JV  job validation
LV  locate/verify
MD  main device scheduler
MF  JES3 monitoring facility
MO  operator modify commands
MS  main service and generalized main scheduling
NT  JES3 networking
OS  output service
PU  purge
RJ  binary synchronous communication remote job processing
SA  mass storage system table create
SN  systems network architecture remote job processing
SS/SI subsystem interface
UT  operator utilities
UX  user exit

The sixth and seventh characters restrict any of the above mnemonics to further classification of a specific task, and indicate (but are not limited to) any of the following:

XM  cross memory processing
DV or DR  driver module for a particular DSP
DT or DA  data CSECT for a particular DSP
CR  card reader processing
MN  monitor

Due to the limited number of combinations provided by 2 characters, there are exceptions to these conventions.

**JES3 internal naming conventions**

Additional conventions are:

- The fourth character of most JES3 executable macros is an X (but there are executable macros that do not follow this convention):
  
  IATX

- The fourth character of a JES3 data area mapping macro is a Y:
  
  IATY

- The fourth character of a JES3 macro that expands within other JES3 macros is a Z:
  
  IATZ

The JES3 nucleus load modules are named:

- IATNUC - JES3 address space
- IATNUCF - C/I FSS address space
- AITNUCI - Initialization stream checker
3.39 JES3 single LPAR

Figure 3-39 shows JES3 in a single-processor environment, also known as a single-system sysplex. Besides the processor, two categories of I/O devices are shown:

- JES3 devices (those used by JES3)
- JES3- and MVS-managed devices (those used by jobs).

The spool device is a direct-access storage device (DASD) that is treated in a special way by JES3, so it is shown and explained separately.

In installations with one processor, the global processor, JES3 coexists in that processor with MVS and with running jobs. In many respects, JES3 is treated like a job by MVS. (That is, MVS handles JES3 in much the same way it handles the jobs it receives from JES3 for processing.) JES3 becomes a processable “job” during initialization, while jobs submitted to the system become processable by the actions of JES3.
Multi-system image

As previously discussed, multiprocessing is a way of doing work with two or more connected processors. In a multiprocessing environment, also known as a multisystem sysplex, JES3 allows up to 32 processors, also known as mains, to be configured into the complex. JES3 uses one processor (called the global) to do work and also to distribute work to up to 31 other processors (called locals).

Figure 3-40 shows a JES3 multiprocessing system that has three processors, that communicate via XCF signalling. The global processor runs most of JES3, for it is from the global processor that JES3 allocates resources to jobs and sends jobs to local processors for processing. In addition, JES3 can also pass jobs to z/OS in the global processor for processing.

Each local processor has a complete z/OS system and JES3 routines for spooling and for communication with the global processor. When z/OS in a local processor needs a job, JES3 in that local processor sends the job request to JES3 in the global processor via XCF signalling. JES3 in the global processor returns identifying information about a job, and JES3 in the local processor uses that information to retrieve the job from the spool device.

If a problem arises on the global processor while JES3 is running, you can transfer global functions to a local processor. This transfer is called dynamic system interchange (DSI). The processor you choose must be capable of assuming the same workload as the previous global.
Availability

If a problem develops with the global processor, you can have one of the other processors assume the global functions (operators have JES3 commands to cause the switch). Jobs running on other processors, including the one to become the new global processor, will usually be unaffected (except for a waiting period until global activities are resumed).

If part of JES3 fails, JES3 collects failure symptoms, records error data, and attempts recovery. All major JES3 components are protected by at least one special JES3 recovery routine. If recovery is unsuccessful, the failing component gets insulated from the rest of JES3, resources are freed, and the failing component will not be used again. If the component is not critical to overall JES3 processing, complete JES3 failure may be avoided.

Workload balancing

JES3 balances workload among processors by considering the resource requirements of jobs. The method JES3 uses is the same whether one or several processors make up the configuration. Thus, addition of another processor does not mean a new operational and scheduling environment.
3.41 JES3 spooling

Spool devices
Most multiprocessing systems use shared data storage. In JES3 the spool device becomes the shared data storage. Thus, besides being a buffer (as for single-processor systems), in multiprocessing systems the spool device becomes a collection point for data to be distributed to individual processors. Also, the spool device becomes a collection point for data coming from local processors routed to JES3 output devices connected to the global processor.

Control flexibility
Operating systems must be easy to control. Internal complexity must be offset by features that make the systems easy to operate, to monitor, and to change. JES3 has designed-in features for operators, application programmers, and system programmers, including:

- Operators have special JES3 commands. Some commands activate programs to handle I/O devices, while others obtain or change the status of jobs being processed. With multiple processing-unit systems, JES3 operators have less to do than for an equal number of individual systems because they can control the entire complex from a central point, and because JES3 decides where and when jobs will be processed.

  JES3 applies installation policies, as defined in the JES3 initialization stream, to perform job scheduling, thus freeing the operator from this task.

  Even though JES3 handles job flow control, there are operational controls in JES3 for the operator to use at his or her discretion to override JES3 decisions, and to take control in unusual situations.
Application programmers have special JES3 control statements (similar to JCL statements). There are control statements to make some jobs run only after successful (or unsuccessful) processing of other jobs, and for specifying the time of day, week, month, or even the year when jobs should run.

System programmers have special JES3 initialization statements to define the way JES3 is to manage devices and jobs. Operators or application programmers can override many of these initialization options on a job-by-job basis. JES3 gives system programmers a unique way of setting installation policy for device and job management. They define separate groups of processing rules. Application programmers select and apply the groups of rules in various ways to individual jobs.

Where JES3 does not provide the exact function that your complex requires, such as special printing requirements, the system programmers can write their own routines and make them part of the JES3 program. This is done through installation exits provided with JES3 and through dynamic support programs that can be added to JES3. For diagnostic purposes, JES3 provides traces and dumps. Traces are copies of data made during normal processing to help monitor activity in the system, and dumps are copies of data made at times of failure.
3.42 JES3 job flow

**JES3 phases of job processing**

Following are the first two phases of processing for a job in a JES3 system:

- **Input service**

  JES3 initially reads all jobs into the global and assigns to each job a unique JES3 job number from the available job number pool. Jobs can be submitted from a locally-attached tape, disk, or card reader. In addition, jobs can be submitted from remote job processing (RJP) workstations, time-sharing option (TSO/E) terminals, other systems in a job entry network, or by the internal reader.

  START and MOUNT commands and TSO/E LOGONs cause jobs to be started from predefined procedures. Input service processes the JCL created for these jobs in the same manner as any other standard job.

  Jobs initially placed on direct-access storage devices (DASD) and subsequently analyzed by JES3 input service are placed on the JES3 spool.

- **Converter/interpreter processing (JCL conversion)**

  JES3 chooses the address space where it converts the job's JCL. The selected address space then reads the job's JCL from spool and converts and interprets the JCL. During this processing, JES3 flushes any job with JCL errors and determines the job-referenced data sets that require volume mounting. JES3 passes the information about the required resources to the JES3 main device scheduler (MDS) if a job requires devices, volumes, or data sets.
3.43 JES3 job flow (2)

**Figure 3-43  JES3 job flow (2)**

### JES3 job flow

After the first two phases, during which jobs are entered into the system and then passed through the converter and interpreter, the next phases are:

- **Main device scheduling (job resource management)**
  
  MDS ensures that resources (devices, volumes, and data sets) needed by the job are allocated before the job processes. MDS sends fetch messages to the tape and disk libraries, and mount messages to the setup operators to mount the volumes needed.

- **Generalized main scheduling (job selection)**
  
  JES3 schedules the job for processing based on specifications determined by the installation.

- **Processing (main service - job execution)**
  
  Jobs can run on the global or a local. z/OS controls the job during this phase. During processing, output generated by the job is usually written to the JES3 spool.

- **Output processing**
  
  Once processing is complete, JES3 processes the job's output data from the JES3 spool. Output data sets are printed and punched by JES3 output service when an available device matches the data set's requirements, such as forms, carriage forms control buffer (FCB), and train. JES3 output service informs the operator of any setup requirements of the data sets. The devices involved can be either local or remote, as defined by the job.
Purge processing

After output processing is complete, the purge function releases all spool space associated with the completed job.

**JES3 from a system programmer's point of view**

One way of visualizing JES3 is as a control program that performs job entry and job exit services. Another way of visualizing JES3 is as a language. Saying that JES3 is a control program is analogous to saying FORTRAN is a compiler. In reality, there is a FORTRAN language and a FORTRAN compiler. Similarly, there is a JES3 language and there is a JES3 program. Just as a FORTRAN programmer uses the FORTRAN language to define work the compiler is to do, JES3 system programmers use the JES3 language to define the work that JES3 is to do.

The JES3 language is made up of initialization statements, control statements, and commands. Operators and application programmers use parts of the language, but it is system programmers who define the total JES3 environment. Often, what is specified on JES3 initialization statements can be overridden with JES3 commands or control statements. While system programmers may not themselves use commands or control statements, they may have to instruct operators or application programmers on when and how they should be used.

A further level of defining how JES3 should do its work comes in the form of installation exits supplied with JES3. For example, in the area of controlling the print output from jobs, a system programmer can:

- Define initial values in the initialization stream
- Allow the operator to make certain modifications to the initial values
- Write an installation exit routine to further modify or control what should happen to the output
3.44 JES3 job flow review

Review of JES3 job flow
Whatever the source of the input, JES3 is signalled that an input stream is to be read. This begins a chain of events that includes:

- Creation and scheduling of a card reader job.
- Reading of the input stream by a DSP.
- Building of JCT entries for each job in the input stream.
- Execution of DSPs represented by scheduler elements in the JCT entries for each job.

The modules that provide this service control the processing at the beginning of a typical MVS job. Input routines create scheduler elements that represent jobs to JES3, process control statements, and group jobs into batches.

**JES3 input service**
Input service accepts and queues all jobs entering the JES3 system. The global processor reads the job into the system from:

- A TSO SUBMIT command
- A local card reader (CR DSP)
- A local tape reader (TR DSP)
- A disk reader (DR DSP)
A remote work station (RJP/SNARJP DSPs)
Another node in a job entry network (NJE DSPs)
The internal reader (INTRDR DSP)

This service reads from the input source and adds jobs to the job queue.

**JES3 converter interpreter**
The converter/interpreter (C/I) is the first scheduler element for every standard job. After a job passes through this first segment of processing, JES3 knows what resources the job will require during execution. C/I routines provide input to main device scheduling (MDS) routines by determining available devices, volumes, and data sets. These service routines process the job's JCL to create control blocks for setup and also prevent jobs with JCL errors from continuing in the system. Main device scheduling provides for the effective use of system resources. JES3 MDS, commonly referred to as "setup," ensures the operative use of non-sharable mountable volumes, eliminates operator intervention during job execution, and performs data set serialization. It oversees specific types of pre-execution job setup and generally prepares all necessary resources to process the job. The main device scheduler routines use resource tables and allocation algorithms to satisfy a job's requirements through the allocation of volumes and devices, and, if necessary, the serialization of data sets.

**JES3 GMS processing**
JES3 generalized main scheduling (GMS) is the group of routines that govern where and when MVS execution of a JES3 job occurs. Job scheduling controls the order and execution of jobs running within the JES3 complex.

**Job execution**
Job execution is under the control of JES3 main service, which selects jobs to be processed by MVS initiators. Main service selects a job for execution using the job selection algorithms established at JES3 initialization. MAINPROC, SELECT, CLASS and GROUP initialization statements control the key variables in the job scheduling and job execution process.

**Output processing**
Output service routines operate in various phases to process sysout data sets destined for print or punch devices, TSO users, internal readers, external writers, and writer functional subsystems.

**Purge processing**
Purge processing represents the last scheduler element for any JES3 job (that is, the last processing step for any job). It releases the resources used during the job and uses the System Management Facility (SMF) to record statistics.
3.45 JES3 job flow: Scheduler elements

JES3 scheduler elements

JES3 processing performed on behalf of jobs consists of distinct phases. A typical job originating in the input stream requires the following phases:

- Converting the job’s JCL to a form usable by MVS.
- Insuring I/O resources needed by the job are available, and passing the job to MVS.
- Handling the job’s SYSOUT data.
- Removing the job from the system.

Each of the four phases of a job is represented by a scheduler element (SE) in the JCT entry for the job shown in the Figure 3-45. Every scheduler element denotes a unit of work JES3 must perform to process the job. Each is represented on the FCT chain by one or more DSPs that performs the work required for that type of SE. Scheduler elements needed for job A are listed here (the actual DSP name is shown in capital letters).

There are two types of jobs in the JES3 complex:

- The standard job
- The non-standard job
Standard jobs

Every job containing JCL is considered a standard job. JES3 places into the JCT entries of all standard jobs the same four scheduler elements in the same order:

- Converter/Interpreter (CI)
- Main service (MAIN)
- Output service (OUTSERV)
- Purge (PURGE)

Each JCT entry contains information about the job and an entry for each SE. Each SE entry contains flags indicating that SE’s status: inactive, active, or complete. JSS uses these flags to determine which SE is next for scheduling/ending functions. The first SE that is not marked complete is selected, and is marked either complete or active.
3.46 JES3 standard job

The names in parentheses are formal names of the DSPs that are executed to perform the work. The number or type of scheduler elements to be used for standard jobs can be changed by means of a user exit routine; such a change would apply to all standard jobs.

JES3 job management consists of the following phases:

- Input service (when the job is read in to the system).
- Converter/interpreter service
- Resource allocation
- Job selection and scheduling
- Output service
- Purge

Note: Resource allocation and JOB selection and scheduling is performed by the MAIN scheduler element.
3.47 JES3 non-standard job

A non-standard job is a job for which the user determines the number of segments and their order of execution. To specify a different set of scheduler elements on a job-by-job basis, code special JES3 control statements and include them with JCL statements for the jobs.

Called jobs, which are non-standard, are created by operator request. The operator uses JES3 *CALL commands to make the requests. Called jobs are unique because they are not defined by JCL; there is, in fact, no JCT involved at all. These jobs are internally generated by JES3 in response to the *CALL command, and their JCT entries always contain two scheduler elements:

- One to represent the DSP needed for the request
- One to remove the called job from the system (PURGE)
3.48 Creating a batch job

Creating batch jobs
For each job in the input stream, ISDRVR creates a JCT entry for each MVS job in the batch.

Information placed into the JCT entry for a job includes:
- A JES3 job number
- The jobname from the JOB statement
- The job priority and class
- A symbolic origin for the job (for returning job output to the origin)
- Information from JES3 control statements
- Scheduler elements representing the DSPs needed to process the job

Since the sample job is a standard job, the scheduler elements will be CI, MAIN, OUTSERV, and PURGE
3.49 Converter/interpreter processing

The CI DSP serves as an interface between JES3 and the JES3 CI subtasks that invoke the MVS converter/interpreter subtasks. The interface responsibilities of the CI DSP are:

- To fail the job if JCL errors are detected by the MVS converter/interpreter
- To fail any job that contains more JCL statements than the limit allows
- To delay processing of any job that would temporarily cause the C/I subtasks to process more JCL statements than the system limit allows
- To copy the SWA control blocks that are produced by the MVS converter/interpreter onto spool

The CI DSP stores I/O requirements in job-related control blocks called the job summary table (JST) and job volume table (JVT). It writes these control blocks to spool along with others for the job. These control blocks and some that are kept in main storage allow JES3 to maintain a complex-wide awareness of the status of volumes and data sets.

During JES3 initialization, JES3 attaches an installation-defined number of converter/interpreter (C/I) tasks. These C/I tasks are subtasks to the JES3 primary task. When a C/I subtask processes a job, the scheduler work area (SWA) in the address space in which the service is invoked (global functional subsystem) provides temporary storage for the job’s JCL statements. These statements remain in the SWA until the C/I subtask finishes processing the job. When several C/I subtasks run concurrently, the SWA contains the JCL statements for all the jobs these subtasks are processing.
3.50 Main scheduler element

Main scheduler element processing

When the MAIN scheduler element is scheduled, the following functions occur under the FCTs, as illustrated in Figure 3-50. Main device scheduling is the allocation of device, volume, and data set resources to jobs, the selection of jobs to be passed to MVS initiators for execution, and the freeing of allocated resources after the jobs are executed.

For standard jobs, main service processing begins when the job segment scheduler reaches the MAIN scheduler element in the job's JCT entry. The MAIN scheduler element represents two DSPs: setup (SETUP) and generalized main scheduling (MAIN). Both of these DSPs are resident and each has a permanent entry in the FCT chain, so the job segment scheduler need not construct the FCT entries.

The work performed by the SETUP and MAIN DSPs is crucial to JES3 processing. The goals of the SETUP and MAIN DSPs are effective resource utilization and maximum job throughput. The processing sequence is:

- Initial setup processing to prepare I/O resources (MDS)
- Generalized main scheduling to select and pass a job to an initiator
- Job execution
- Breakdown processing to relinquish I/O resources

Figure 3-50  Main scheduler element
3.51 Main device scheduling (MDS)

- **MDS processing options**
  - Volume fetch
  - Job setup
  - High watermark setup (HWS)
  - Explicit setup - //*/MAIN SETUP=
  - NONE - (makes MDS optional)

- **Schedules resources to jobs**
  - Devices - volumes - data sets

- **Objectives**
  - Satisfy resource requirements before execution

**Main device scheduling**

Main device scheduling (MDS) represents the second phase of setup processing. Converter/interpreter is the first phase. The converter/interpreter routines construct a job summary table (JST) that lists required data sets and devices, and a job volume table (JVT) that describes the volumes the main's device scheduling routines will fetch and allocate. Volumes that are mounted will be verified.

Main device scheduling functions are optional and may be bypassed for a job as well as a complex. The purpose of MDS is to allocate I/O resources among competing jobs and release resources after they have been used. JES3 setup processing is defined by JES3 initialization statement parameters, JCL control statements, and JES3 operator commands. JES3 setup is available through the following options:

- Volume fetch
- Job setup
- High-watermark setup
- Explicit setup
3.52 Main scheduler element processing

- Generalized Main Scheduling - GMS
  - User defined algorithms - jobs to initiators

- Job execution
  - Monitor jobs during execution
  - Operator communication

- Main device scheduling - Breakdown
  - Return resources - devices, volumes, data sets

Figure 3-52  Main scheduler element processing

Main scheduler element processing

JES3 job scheduling is the group of routines that govern where and when MVS execution of a JES3 job occurs. Job scheduling controls the order and execution of jobs running within the JES3 complex.

Job scheduling involves the routines invoked by the MAIN DSPs, which are represented by the MAIN scheduler elements on the job control table entry.

GMS selects jobs to be processed by MVS initiators. GMS selects a job for execution using the job selection algorithms established at JES3 initialization. MAINPROC, SELECT, CLASS, and GROUP initialization statements control the key variables in the job scheduling and job execution process.

During execution, the operator can monitor and cancel jobs.

When a step completes or the job ends, MDS breakdown occurs, which allows the freeing of resources, devices, volumes, and data sets.
3.53 OUTSERV scheduler element processing

OUTSERV scheduler element processing phases
Following are the processing phases for output processing:

- Phase 1 - Queuing of output
- Phase 2 - Scheduling of output
- Phase 3 - Printing and punching of output

Phases 1 and 2 occur in the JES3 global address space on the global processor. Phase 3 can run in the global address space or in a functional subsystem (WTR FSS).

- The OUTSERV DSP summarizes output data sets at two points of processing:
  - For normal jobs, when a job completes main service processing
  - For spin-off data sets, when a job or a DSP moves a data set directly to output service for processing before the job ends
- JES3 creates output service elements (OSEs) to summarize the output data set characteristics for scheduling. An OSE represents all of a job’s output data sets with similar scheduling characteristics. One job can have several OSEs. OSEs are later used to schedule output to specific devices.
- The JES3 WTR DSP handles printing and punching of output. The WTR DSP reads from spool and writes to the specific output device, thereby performing device dependent functions. Output can be sent to a variety of devices. For locally attached devices that are driven by JES3 in the global address space, the WTR DSP writes directly to the device. For non-locally attached devices that are not driven by the JES3 global address space, the WTR DSP passes output to the appropriate interface. This can be RJP, SNARJP, NJE services, the internal writer, or a functional subsystem (FSS).
3.54 Output service processing

Output writers
- Hot writers - *X WTR,........
- Dynamic writers

Output types processed
- Print and punch
- External writer - PSO
- TSO users via OUTPUT command - PSO

10 user exits

SMF type 6 records

Output service processing
Hot writers give operations personnel total control of output handling. Operators enter commands to call and control hot writers. Hot writers remain available, even when there is nothing to print.

Dynamic writers are often used for volume printing on stock paper. These writers allow JES3 to control changing the setup characteristics for devices, thereby reducing the amount of control operators have over when and how writing is performed.

The output types processed are by device type. This characteristic indicates which type of device is to receive the output. Data sets that were defined as “print type” will be sent to printers, “punch type” will be routed to punches, and “sys type” will be routed to TSO or to external writers.
3.55 Purge processing

Purge processing represents the last scheduler element for any JES3 job (that is, the last processing step for any job). It releases the resources used during the job and uses the System Management Facility (SMF) to record statistics. Purge processing consists of the following steps:

- JES3 releases all spool space assigned to the job and updates resident control blocks.
- JES3 writes SMF record type 25, which contains device allocation information.
- JES3 writes SMF record type 26, which contains final job accounting information.
- JES3 informs the operator that the job has been purged.
- The JCT entry is deleted.

Figure 3-55  Purge processing
3.56  JES3 functions not in JES2

- Main Device Scheduling (MDS)
- Generalized Main Scheduling (GMS)
- Dependent Job Control (DJC)
- Deadline scheduling
- Interpreter processing
- Priority aging

Figure 3-56  JES3 functions not in JES2

Main device scheduling
JES3 provides a device management facility called the main device scheduler (MDS) that can wholly or partially support the MVS allocation process. The purpose of MDS is to satisfy job resource requirements (the devices, volumes, and data sets needed) before and during job execution, thus allowing execution to proceed without allocation delays. MDS also allows controlled multisystem access to commonly accessible data sets in the loosely coupled environment.

Generalized main scheduling
Each time an MVS initiator requests work, generalized main scheduling (GMS) selects and schedules a job for execution. The job that GMS selects depends primarily upon initialization parameters that you have specified. Deadline scheduling and dependent job control (DJC), additional GMS functions, enable you to control when jobs execute. With deadline scheduling, you specify a deadline by which you want the job to run. JES3 periodically increases the job's selection priority in an attempt to run the job by the specified deadline. DJC allows you to create a network of related jobs.

Dependent job control
Dependent job control (DJC) is a means of coordinating the processing of jobs. With DJC, one job will not run unless some other job has run first. (DJC has an MVS counterpart for conditional execution of job steps.) DJC requires no advance preparation with JES3.
initialization statements. Application programmers can specify all relationships between jobs on JES3 control statements they submit with the affected jobs.

**Deadline scheduling**
Deadline scheduling is a way of scheduling jobs by time of day or by week, month, or year. Job priorities remain in force, but as deadlines approach, JES3 increases the priorities, thereby increasing the likelihood the jobs will be processed before a certain deadline. System programmers must prepare for deadline scheduling with JES3 initialization statements that tell when a priority is to be increased, and by how much. Then application programmers can put deadlines on JES3 control statements they include with the jobs.

**Interpreter processing**
Converter/Interpreter (C/I) service controls the conversion of JCL statements to Converter/Interpreter text and then into control blocks. This service comprises primarily the JES3 CI and POSTSCAN dynamic support programs, the C/I subtasks under which the MVS C/I routines run, and the initiator support routines. C/I service controls the conversion and interpretation of a job's JCL. The three principal phases of C/I service are:

- **Converter/Interpreter phase:** Uses the MVS C/I routines to convert and interpret JCL into scheduler control blocks. At this time, the scheduler control blocks are created in the scheduler work area (SWA).
- **Prescan phase:** Extracts job requirements from the scheduler control blocks for use in the postscan phase. At the end of the prescan phase, the scheduler control blocks are moved from the SWA to JES3 spool.
- **Postscan phase:** Locates data sets and gathers information for use in JES3 device setup.

**Priority aging**
When all initiators are busy, throughput of certain jobs might fall below normal expectations. To help in these situations, JES3 uses the additional scheduling function of priority aging. Priority aging can help ensure that jobs that have been waiting to run have a chance of being selected to run before those jobs that just entered the system. By using priority aging, an installation can increase the priority of a waiting job. The longer the job waits, the higher its priority becomes, up to a limit, and the greater its chances of being selected to run.
3.57 Dynamic support program (DSP)

- JES3 functions called DSPs
  - Readers, writers, converters, .... etc.
  - Many functions started automatically
  - Other functions started by the operator
    - Operator callable DSPs  *X dspname
    - Called DSPs become JES3 jobs

*X WTR,OUT=PRT1

$S PRT1 (JES2)

Figure 3-57 Dynamic support program (DSP)

Dynamic support programs (DSPs)
Each small piece of work that JES3 performs when processing a job is accomplished with a JES3 program called a dynamic support program, or DSP. Each DSP is presented on the FCT chain by one or more FCT entries or elements. The elements on the FCT chain are executed according to their priority, and are placed on the FCT chain with the high priority element first. The higher priority elements are executed before the lower priority elements.

JES3 dynamic support programs (DSPs) control JES3 processing. Some primary DSPs (such as MAIN) directly relate to a job's execution. Other DSPs (such as Dump Job and Disk Reader DSPs) provide functions or services that can be called by a system operator.

In addition to the JES3 DSPs, you can create your own DSPs and add them to the system. Such DSPs run enabled in supervisor state, and under protection key 1. They become part of JES3, and JES3 expects them to use the same programming conventions as JES3 DSPs supplied by IBM. Examples of DSPs provide by JES3 are readers, writes, converts, and so on.

To execute a DSP:
1. Issue the *CALL command to make the DSP available to the system (that is, added to the FCT chain).
2. Issue the *START command to start processing the DSP.

To stop a DSP, issue the *CANCEL command.
3.58 JES3 and consoles

- JES3 may be operated from any console attached to any system.
- From any console, an operator can:
  - Direct a command to any system
  - Receive the response to that command
- Any console can be set up to receive messages:
  - From all systems
  - Specific systems

Figure 3-58  JES3 and consoles

JES3 and consoles
JES3 may be operated from any console that is attached to any system in the sysplex. From any console, an operator can direct a command to any system and receive the response to that command. In addition, any console can be set up to receive messages from all systems, or a subset of the systems in the sysplex. Thus, there is no need to station operators at consoles attached to each processor in the sysplex.
3.59 Issuing commands

**Figure 3-59 Issuing commands**

**Command processing**

You must establish a command prefix for each JES3 system since commands are routed also by the prefix. The routing of commands occurs as follows:

- **Command prefix and CMDSYS routing**
  
  If the command contains a prefix or the console has a CMDSYS specification that directs the command to another system, the command is immediately transmitted using XCF services to the processing system.

  **Note:** For command prefix and CMDSYS routing, the command is first transported to the receiving system before any system symbol substitution takes place.

A REPLY command is sent to the system where the WTOR was issued. If the REPLY command text contains system symbols, substitution occurs on the receiving system.

- **MPF command user exit**
  
  If the command is not transmitted to another processing system, it is processed on the issuing system by the installation MPF command exit routines. The exits are specified using the .CMD statement in the MPFLSTxx parmlib member. These exits can perform authority checking, modify the command text, or the command processing.
SSI processing

The command is broadcast on the subsystem interface (SSI) to all active subsystems. Each subsystem inspects the command and decides whether to process it. The subsystems base the decision on the command prefix characters of the command string. For example, by default, NetView looks for a percent sign (%) and process the commands starting with the % sign.

When a subsystem decides to process the command, the command is passed to subsystem processing, and a return code is set to indicate that the command was processed by a subsystem.

Note: At this point in processing, all system symbol substitution has occurred. The original command text is also available.

Hardcopy log

Once the command has been examined by all active subsystems, it is logged to the &hc.log (usually SYSLOG or OPERLOG).

Note: The hardcopy log contains the command before any system symbols contained in the command have been substituted, and it also contains the command after substitution has occurred.

MVS command processing

If none of the subsystems has marked the command as having been processed, it is assumed to be an MVS command and passed to the appropriate MVS command processor. If a command processor does not exist, an error message is issued stating that the command is invalid.
Defining consoles

Consoles are devices that you use to enter commands and receive messages from JES3, MVS, and application programs. Consoles fall into one of the following classes:

- Multiple console support (MCS) consoles
- Remote job processing (RJP) consoles

MCS consoles are devices that you can physically attach to global or local processors. These consoles allow you to control the sysplex. Refer to z/OS MVS Planning: Operations, SA22-7601 for information about MCS consoles in a sysplex environment.

RJP consoles are devices that you attach to the JES3 global as part of a remote workstation using telecommunications lines. RJP permits you to submit jobs and receive output at workstations that can reside at some distance from your installation.

See z/OS JES3 Initialization and Tuning Reference, SA22-7550 for more information about defining RJP consoles.
3.61 JES3 commands

- *INQUIRY commands are used to request information - (*I)
- *MODIFY commands used to change specifications in jobs - (*F)
- *CALL (*X), *START (*S), *RESTART (*R), *CANCEL (*C), and *FAIL commands used to control dynamic support programs (DSPs)
- *VARY (*V) commands and the *MODIFY,V (*F V) command are used to control devices and other JES3 resources
- *SWITCH and *FREE commands used to control RJP consoles
- *MESSAGE commands are used to communicate with other consoles and with remote nodes
- *SEND (*T) commands route commands to a remote node
- *DUMP and *RETURN are used to terminate JES3

Figure 3-61 JES3 commands

JES3 operator control

Commands are requests you make to the system. You can use commands to control devices, to change specifications previously made to the system, or to display information about the operator's console. The first element of a command is a prefix that informs JES3 that a command is being entered. The default JES3 command prefix is the asterisk character (*).

These are the basic JES3 commands and their purposes:
- *INQUIRY commands are used to request information. No action will be taken except that the requested information will be displayed.
- *MODIFY commands are used to change specifications given in jobs or previous commands, or during initialization.
- *CALL, *START, *RESTART, *CANCEL, and *FAIL commands are used to control dynamic support programs (DSPs), such as utilities.
- *VARY commands and the *MODIFY,V command are used to control devices and other JES3 resources.
- *SWITCH and *FREE commands are used exclusively to control RJP consoles.
- *MESSAGE commands are used to communicate with other consoles and with remote nodes.
- *SEND commands are used to route commands to a remote node.
- *DUMP and *RETURN commands are used to end JES3.
- *TRACE command is used to trace certain JES3 events.
3.62 Controlling JES3 jobs

Use the *MODIFY,J= or the *F,J= command to:

- Hold a job, *F,J=nnnn H
- Release a job, *F,J=nnnn R
- Cancel a job, *F,J=nnnn C or CP or CO
- Change a job's priority, *F,J=nnnn P=nn
- Change a job's job class, *F,J=nnnn C=class
- Change a job's JESMSGLG logging status, *F,J=nnnn LOG or NOLOG

Use the *MODIFY,Q or *F,Q command to:

- Hold or release all the jobs in the JES3 job queue, *F Q H or R
- Hold or release jobs of a designated priority, *F Q P=nnn H or R
Controlling job input

Each small piece of work that JES3 performs when processing a job is accomplished with a JES3 program called a dynamic support program, or DSP. Each DSP is represented on the FCT chain by one or more FCT entries or elements. The elements on the FCT chain are executed according to their priority, and are placed on the FCT chain with the high priority element first. The higher priority elements are executed before the lower priority elements.

**IATYDSD macro**
The IATYDSD macro generates an entry for a dynamic support program (DSP) in the DSP dictionary (module IATGRPT or, in a C/I FSS address space, module IATGRPTF). An entry in the table is required for each DSP in order for it to be recognized as part of JES3. The following are considerations:

- **ISDRVR**: The 1 to 8 character name of the DSP whose entry is being created by this macro. If the DSP is to be callable, this name will appear as the argument of an *X,dspname command. If the DSP is to be processable, this name will appear in the //*PROCESS dspname JCL statements. The label is required.
- **PRTY**: The priority to be assigned to the DSP, in the range from 1 through 255. This priority becomes the FCT priority when the DSP is activated.
- **REENT**: Specifies that the DSP is reenterable.
- **DRVR**: The name of the DSP driver module to be loaded, if necessary, for each use of the DSP.

---

**Figure 3-63  Controlling job input**

**DSP dictionary entry for ISDRVR**

```
ISDRVR IATYDSD PRTY = 4,PABLE = YES, *
       CSECT = IATISDT,REENT = YES, *
       DRVR = IATISDV,MAXCT = 2
```

**Inquiry DSP entry ISDRVR**

```
*I X,D=ISDRVR
IAT8475 (IQDX) - ISDRVR  MXCT=000002  USE=000000  MOD=YES
IAT8472 (IQDX) - ISDRVR  IS NOT IN HOLD
```

**Modify DSP entry ISDRVR**

```
*F X,D=ISDRVR,MC=5
IAT8484 (MODX) - ISDRVR  OLDMXCT=000002  NEWMXCT=5
```
CSECT  The name of the data CSECT to be loaded by the job segment scheduler driver (module IATGRJR) for each use of the DSP.

MAXCT  The maximum number of copies of this DSP that may be concurrently active. The number must be within the range 1 through 65535. If this parameter is not specified for a DSP specifying REENT=YES, no MAXCT limit is imposed. This parameter is dynamically alterable by using the *MODIFY command unless you specify MUCC=NO.

JSS schedules all DSPs into execution by building an FCT and adding the FCT to the FCT chain in priority sequence.
3.64 Commands for job queue status

Displaying job queue status

Use the *INQUIRY,Q command to display:

- A list of jobs waiting for a DSP.
- The names of the spool data sets assigned to a spool partition and whether the partition is defined as the default partition, the initialization partition, or an overflow partition.
- The size of the partition and the amount of space currently available.
- The status of a partition, and users of the largest spool space.
- The status of a spool data set and the name of the spool partition the data set belongs to.
- All the defective tracks currently known to JES3.
- The amount of space available on all the JES3 spool data sets in the complex.
- A list of jobs of a particular category in the JES3 job queue.
- The amount of space remaining in the JES3 job queue.
- The status of the spool integrity function.
- A list of jobs that use the specified scheduling environment that are either waiting to be scheduled or have been scheduled for main service. Information about why the job is waiting can also be displayed.
- A list of jobs with the specified service class that are either waiting to be scheduled for main service or have been scheduled for main service. Information about why the job is waiting can also be displayed.
- Whether or not multiple batch jobs with the same name may be scheduled for the MAIN SE at the same time.

You might want to use this command to help determine if a performance problem is the result of JES3 using a high percentage of the available spool space in one or more spool partitions.
3.65 Jobs in operator hold

You can use the command *I Q,H,OP to display the status of all jobs in operator hold, with the total summary count.

You can use the option H to display the status of jobs held with:

- Operator hold
- DJC operator hold
- Error hold
- Spool hold
- Priority hold
- DJC net hold
- Automatic restart management hold
3.66 Jobs in hold

Command for jobs in hold

The output of the *I Q,H command is shown in Figure 3-66.

If you use the SUMM option you will display the summary of jobs for each hold type.
3.67 Managing output service jobs

**Commands for job output**

Use the \*INQUIRY, U or the \*I, U command to display job output in a JES3 system. The job output can be at various places within the system and your selection of the proper Q= keyword value on the \*INQUIRY, U command dictates what output you want.

The choices are generally the following:

- **\*INQUIRY, U, Q=BDT**
  - To display SNA/NJE job output.

- **\*INQUIRY, U, Q=HOLD**
  - To display job output on the HOLD queue.

- **\*INQUIRY, U, Q=WTR**
  - To display job output on the WTR service queue.

- **\*INQUIRY, U**
  - To display job output on the WTR service queue. (Q=WTR is the default.)

A command can have a length of up to 126 characters if the command is issued from an input device that permits that command length.
3.68 Start JES3 with a hot start

- After an orderly shutdown
- After a JES3 failure on the global from which JES3 cannot automatically recover
- After an MVS failure that terminates all functions in the global
- To replace one of your checkpoint data sets
- Warm start requires IPL of all systems

Starting JES3
Use a hot start to start JES3 on the global:
- After an orderly shutdown
- After a JES3 failure on the global from which JES3 cannot automatically recover
- After an MVS failure that terminates all functions in the global
- To replace one of your checkpoint data sets

JES3 does not read the initialization stream during a hot start. Instead, JES3 initializes itself by using the parameter values established during the previous cold or warm start. In addition, certain changes made by the operator after the previous restart remain in effect. For a list of these changes, see z/OS JES3 Commands, SA22-7540-03.

If you perform an IPL of MVS before the hot start, JES3 restarts jobs that were running on the global and are eligible for restart. If a job is not eligible for restart, JES3 processes it based on the job’s failure options. For an explanation of the failure options, see the FAILURE parameter on the CLASS initialization statement. JES3 also restarts all FSSs that were running on the global and reschedules all jobs that were active in the FSS at the time of the IPL. If you do not perform an IPL of MVS before the hot start, all jobs and FSSs that were running before the hot start continue to run after the hot start. During a hot start, JES3:
- Examines the job queue to verify that it can restart each job
- Prompts the operator if it locates a job that contains invalid control information
- Removes jobs that contain invalid control information
- Records the job control information associated with the removed jobs (they are recorded in the data set defined by the //JES3SNAP DD statement)
- Continues to process valid jobs that were in the job queue before the hot start. Internal job numbering resumes with the next available job number.

Jobs and FSSs running on locals before the hot start continue to execute after the hot start. Any changes to the definition of an FSS brought about by using the *MODIFY operator command before the hot start remain in effect across a hot start with or without an IPL of MVS. Overflow partition relationships, including any changes brought about by using the *MODIFY operator command before the hot start, also remain in effect across a hot start.

**Warm start**

Use a warm start to restart JES3 on the global:
- After either type of hot start or hot start with refresh fails.
- After a failure of the global because of a software/hardware failure.
- When you want to change the initialization stream and the changes cannot be performed with a hot start with refresh.
- Following the construction of the MVS Base Control Program.

During a warm start, JES3 reads and processes the initialization stream, saves jobs that are in the job queue, and terminates active jobs according to the job’s failure options.

After a warm start, you must IPL and then restart all local processors. All FSS address spaces terminate at IPL time and are restarted by JES3 after IPL. JES3 then reschedules all jobs that were active in the FSS address space at the time of warm start. Any changes to the definition of an FSS address space brought about by using the *MODIFY operator command before the warm start are lost. JES3 continues to process jobs that were in the job queue at the time of the warm start.
3.69 JES3 DLOG function

JES3 DLOG function

JES3 provides an option to activate a DLOG, where records are written in the JES3 format rather than the MVS format.

The DLOG message traffic is managed by MCS. On the global, JES3 activates an extended MCS console with the HARDCOPY=YES attribute to receive the hardcopy message set. The messages received by the DLOG EMCS console are in the MDB format and are converted to the JES3 DLOG format and then written using the WTL macro service to the global JES3 system's SYSLOG (alias DLOG).

JES3 initialization assigns SYSLOG unconditionally to be the MVS hardcopy medium (VARY SYSLOG, HARDCPY) on all systems. If a hardcopy log to a device is required (MLOG is requested in the initialization stream), it is written by JES3 to a JES3-managed device. In addition, if DLOG is specified in the initialization stream, and the JES3 global is restarting without IPL, JES ensures that the log is active on the global processor (WRITELOG START). During local connect processing, JES3 causes the accumulated log data on each local to be written to spool (WRITELOG).

When JES3 is installed, you have the option to use the OPERLOG as the only hardcopy media. Because JES3 can no longer unconditionally assign SYSLOG to the MVS hardcopy media (VARY SYSLOG, HARDCPY) on all systems, this processing is removed. However, if DLOG is requested in the initialization stream, JES3 global initialization continues to ensure that SYSLOG is assigned the hardcopy media and that a SYSLOG task in the console address space is active.

The initial state for DLOG is defined on the CONSTD initialization statement with the parameter DLOG=ON or DLOG=OFF, as shown in Figure 3-69 on page 229. The old CONSTD keyword HARDCOPY= is deleted.

The operator can turn the DLOG on or off with a command.

---

3.69 JES3 DLOG function

- DLOG started as address space on global
  - Establishes EMCS console
  - Receives messages from all systems in sysplex
  - Formats messages in JES3 format
    - Writes to SYSLOG
- Operator command to start or stop DLOG
  - "F O,DLOG=ON|OFF"

Figure 3-69 JES3 DLOG
3.70 JES3 start procedure

```
//JES3     PROC
//IEFPROC  EXEC PGM=IATINTK,DPRTY=(15,15)
//STEPLIB  DD DISP=SHR,DSN=SYS1.VnRnMn.SIATLIB
//CHKPNT   DD DISP=SHR,DSN=SYS1.JES3CKPT
//CHKPNT2  DD DISP=SHR,DSN=SYS1.JS3CKPT2
//JES3JCT  DD DISP=SHR,DSN=dsn
//SPOOL1   DD DISP=SHR,DSN=dsn
  .
  .
//SPOOLnn  DD DISP=SHR,DSN=dsn
//JES3OUT  DD DISP=SHR,DSN=dsn
//JES3SNAP DD UNIT=AFF=JES3OUT
//JESABEND DD UNIT=AFF=JES3OUT
//SYSABEND DD UNIT=AFF=JES3OUT
//JES3DRDS DD DISP=SHR,DSN=dsn
//IATPLBST DD DISP=SHR,DSN=SYS1.PROCLIB
  .
  .
//IATPLBnn
//JES3IN   DD DISP=SHR,DSN=SYS1.PARMLIB(JES3IN00)
```

Figure 3-70  JES3 start procedure

How to start JES3

JES3 runs as a started task in the z/OS environment. Therefore, z/OS must be active before you can start JES3. Moreover, JES3 must be active on the global before you can start JES3 on the local mains.

The required JES3 procedure DD statements are explained as follows:

**IEFPROC**
Specifies the name of the JES3 job step task, load module IATINTK.

**CHKPNT and CHKPNT2**
Define the JES3 checkpoint data set(s). At least one of the two checkpoint data sets must be allocated and cataloged prior to JES3 operation. Each checkpoint data set must be allocated as a single extent which begins and ends on a cylinder boundary. The size of each data set should be at least 2 cylinders on a 3380, 3390, or 9345 spool volume.

**JES3JCT**
Defines the JES3 job control table (JCT) data set. This data set must be allocated and cataloged prior to JES3 operation. The data set must be large enough to accommodate the maximum number of JCT records to be allocated concurrently during normal system operation.

**Spool1 and Spoolnn**
Define the spool data sets. The installation selects the ddnames and data set names for these statements. The ddname for this statement must be the same ddname specified...
on the BADTRACK, FORMAT, or TRACK initialization statements. Spool data sets must be allocated and cataloged prior to JES3 operation.

**JES3OUT**

Defines the data set upon which the JES3 initialization stream and initialization error messages are printed. This data set is de-allocated after initialization completes. You can tailor the block size (BLKSIZE) and logical record length (LRECL) values to improve performance. The values you can specify are device-dependent.

**IATPLBST**

Defines the installation's standard procedure library.

**JES3IN**

Defines the data set containing the JES3 initialization stream. This data set must be a blocked or unblocked partitioned data set. In our example, the initialization stream is read from SYS1.PARMLIB(member JES3IN00).
3.71 JES3 initialization stream

Figure 3-71 JES3 initialization stream

JES3 initialization deck
Here are the required JES3 initialization statements:

- **DEVICE,DTYPE=SYSMAIN,JNAME=main1,JUNIT=(,main2,,OFF|ONÀ,...)**
  
  Use this form of the DEVICE statement (there are two other forms of the DEVICE statement) to define the initial status of mains in a JES3 complex. You must code one of these DEVICE statements for each main on every processor in the complex, as follows:

  ```
  DEVICE,DTYPE=SYSMAIN,JNAME=SY1,JUNIT=(,SY1,,ON,)
  ```

- **ENDINISH**
  
  Use the ENDINISH statement to identify the end of the initialization statements in the initialization stream.

- **ENDJSAM**
  
  Use the ENDJSAM initialization statement to indicate the end of the JES3 spool initialization statements.

- **FORMAT,DDNAME=ddname,SPART=partitionname {,STT=(cylnum,cylnum)}
  {,STTL=(cylnum,numtrkgps)}**
  
  Use the FORMAT statement to specify formatting for a data set residing on a direct-access spool volume during initialization. Specify this statement only when
introducing an unformatted volume into a JES3 system or when you change the BUFSIZE parameter on the JES3 BUFFER initialization statement as follows:

```
FORMAT, DDNAME=SPPOOL1, STT=(30, 31), SPART=PART1
```

The corresponding DD statement in the JES start procedure is:

```
//SPPOOL1 DD DSN=dsn, DISP=OLD, UNIT=SYSDA, VOL=SER=xxxxxx
```

Use the MAINPROC initialization statement to define a uniprocessor or a multiprocessor as a JES3 main. The initialization stream must include one MAINPROC statement for each main that you wish to define to JES3. Each MAINPROC statement must have a DEVICE statement that specifies DTYPE=SYSMAIN associated with it.

The NAME=main specifies the name of a JES3 main. The name should match the purpose of the main, or at least the hardware it is using. You also use this name in operator commands and in the JES3 CLASS, DEVICE, GROUP, MSGROUTE, and SETACC initialization statements to refer to the main. It must be the first or second parameter on the statement.

The SPART=partitionname specifies the spool partition that JES3 is to use for jobs that execute on the main defined by this statement. To specify the default spool partition, omit the SPART parameter.

```
TRACK, DDNAME=ddname, SPART=partitionname {, STT=(cylnum, cylnum)}
{, STT=(cylnum, numtrkgps)}
```

Use the TRACK initialization statement to replace a corresponding FORMAT statement in an initialization stream after the spool data set specified by the FORMAT statement has been formatted. The TRACK statement indicates that the corresponding data set has been formatted.

```
TRACK, DDNAME=SPPOOL1
TRACK, DDNAME=SPPOOL2
```

Depending on how your z/OS initial program load (IPL) procedures are set up, JES3 can be started automatically or you can start JES3 manually by entering a z/OS START command from the master console. The manual method allows you to determine if the IPL and system configuration conditions are acceptable before starting JES3. If the JES3 subsystem definition in the IEFSSNxx parmlib member specifies the NOSTART subparameter, JES3 must be started manually. Otherwise JES3 will start automatically.
3.72 JES3 startup messages

Figure 3-72  JES3 startup messages

JES3 messages during a start

Figure 3-72 shows the messages that are displayed when you start JES3. The first message shows the status of JES3 processors in the complex; after that, JES3 sends a request to the operator asking him the type of start.

Here are the ways to start JES3:

- Hot start
- Hot start with analysis
- Hot start with refresh
- Hot start with refresh and analysis
- Warm start
- Warm start with analysis
- Warm start to replace a spool data set
- Warm start with analysis to replace a spool data set
- Cold start
- Local start (used to start local mains only)

The type of start you select depends on why you need to start or restart JES3. In our example the operator chose hot start (h). During hot start JES3 displays information about the spool configuration as well as other information, as shown in Figure 3-72.
3.73 JES3 startup

After a successful system hot start, the messages in Figure 3-73 are displayed. To start scheduling jobs the operator has to issue the following command.

*S JSS

Before starting job scheduling, you can use JES3 commands to cancel jobs, change the status of jobs, and change the status of devices. During a hot start with analysis, you can release jobs in spool hold status after reinstating a spool data set that contains data for the jobs, and you can vary devices online or offline. You can make adjustments for any system data that might have been lost during the restart.

You can also make any changes to the system that were made before a hot start or a warm start, but did not remain in effect after the restart. When you are satisfied that the system is ready to begin processing, enter a *START,JSS command to start job scheduling.
3.74 JES3 messages following *S JSS

The messages shown in Figure 3-74 are displayed by JES3 to indicate which functions are active and other actions that JES3 took during job scheduling initialization.

It also shows that the system is connected to the complex and which initiators are available (started) for job processing.
3.75 JES3 start types

The types of starts and restarts for the JES3 global processor are shown in Figure 3-75. You must use a cold start when starting JES3 for the first time. For subsequent starts (restarts), you can use any one of the start types, depending on the circumstances at the time. Thus, the other types of starts are actually restarts.

JES3 initialization statements are read as part of cold start, warm start, and hot start with refresh processing. If JES3 detects any error in the initialization statements, it prints an appropriate diagnostic message on the console or in the JES3OUT data set. JES3 ends processing if it cannot recover from the error. In this case, you must notify the system programmer to ensure that the error is corrected before restarting JES3.

JES3 configuration and processing options are specified with the initialization statements. Because many options affect the overall performance of the system, initialization statements must be provided by your system programmer. After starting JES3 on a local main, you can use the ROUTE command to start JES3 on all the local processors once JES3 global initialization is complete. For example:

```
ROUTE *OTHER,S JES3
```

**JES3 local start**

Use a local start to restart JES3 on a local main after a normal shutdown on the local, after JES3 ends due to a failure in either the local JES3 address space or z/OS, or after partitioning a multiprocessor. You must also start each local main after you perform a cold
start or any type of warm start on the global, or after you use a hot start to remove or reinstate a spool data set on the global processor. You can perform a local start any time the global is active. Local start processing uses the initialization stream placed on the spool data sets during global main initialization.

**Note:** Do not start a main if another main having the same name is active in the complex.

Before you begin, be sure that all spool data sets available to the global are also available to this local.

**Start JES3**

If you are performing an IPL of the local main and the MSTRJCL contains the automatic **START** command, the command is displayed on your console immediately after the z/OS master scheduler is initialized. You can enter the z/OS command:

```
START JES3
```

The first message from JES3 is:

```
IAT3040     STATUS OF JES3 PROCESSORS IN COMPLEX
main(status) (,main(status)...)  
```

A series of entries on the following lines of the message contain the name of each main followed by a code for that main’s status as recorded in the complex status record (CSR). During a start for the system, this entry (the status of the global) is:

```
main< >
```

On subsequent starts, this entry could be:

```
main<IN>
```

This indicates that the previous start ended abnormally during initialization; this main is still recorded in the CSR as being in initialization as follows:

```
main<UP>
```

This main is recorded in the CSR as currently being active (up). Consult with the system programmer before continuing with a cold start.

Next, JES3 issues the following message:

```
n IAT3011 SPECIFY JES3 START TYPE:(C, L, H, HA, HR, W, WA, WR, WAR OR CANCEL)
```

To continue the start, enter the appropriate letters shown in the message, as follows:

```
R nn,C
```

To cancel the start, enter:

```
R nn,CANCEL
```
Start JSS

After JES3 initialization has finished, you should start the job segment scheduler (JSS). You start job scheduling after JES3 issues message IAT3100 notifying you that initialization processing is complete on the global:

IAT3100  JES3 xxxxx SYSTEM type START ON yyyy.ddd AS main

where xxxxx is the release level of JES3; type is COLD, WARM, or HOT; yyyy.ddd is the Julian date; and main is the JES3 name of the main.

Before starting job scheduling, you can use JES3 commands to cancel jobs, change the status of jobs, and change the status of devices. During a hot start with analysis, you can release jobs in spool hold status after reinstating a spool data set that contains data for the jobs, and you can vary devices online or offline. You can make adjustments for any system data that might have been lost during the restart. You can also make any changes to the system that were made before a hot start or a warm start but did not remain in effect after the restart.

When you are satisfied that the system is ready to begin processing, enter the following command to start job scheduling:

*START,JSS

After you enter the *START,JSS command, ensure that the global is varied online to JES3. If it is not, enter the *MODIFY,V,main,ON command to vary the processor online, ensuring that the subsystem interface, the z/OS system commands, and the system log are initialized.

JES3 then issues the following message:

IAT2645  ***** main CONNECT COMPLETE *****

If you do not want the global to run jobs, you can now vary the main offline to JES3 scheduling with the *MODIFY,V,main,OFF command. At this point, you can resubmit any jobs that were canceled or whose processing was altered as a result of the restart.

How to stop JES3

Stopping JES3 can be done on either of the global and local systems, as follows:

Stopping local processors

Before you remove a local main for maintenance or other reasons, allow processing jobs to complete normally. Use the following steps:

1. Enter a *F,V,main,OFF command for the local main to prevent JES3 from scheduling any further jobs on the processor.
2. Enter the *RETURN command with the proper password to end JES3 after all jobs on the local main have completed processing.

3. Enter the HALT EOD command on the local main to ensure that important statistics and data records in storage are not permanently lost.

Your installation may not want to wait for all jobs to complete normally, for example:

- Jobs will not end due to system problems (hardware and software)
- An IPL or JES3 restart is scheduled to take place at a predetermined time and jobs will not be able to complete. In this case, you must make the decision to delay the IPL or to cancel the jobs.

**Note:** Enter the HALT EOD command only if you are performing an IPL or SYSTEM RESET, not to restart JES3.

**Stopping the global processor**

Before stopping the global, you should stop the local mains as described previously. You should stop all JES3 processing by entering the *F,Q,H command, which puts all jobs in hold status before stopping JES3. System initiators, printers, and punches do not begin any new work, and become inactive after completing their current activity. Jobs in JES3 queues remain in their current position.

You should also queue the system log for printing by entering the WRITELOG command. This prevents log messages from being lost if you later restart JES3 with a hot start.

Once all system activity has completed, enter the *RETURN command to end JES3.

*RETURN,password,FSS=fssname or
*RETURN,password,FSS=ALL or
*RETURN,password,FSS=NONE

After you enter the *RETURN command, enter the HALT EOD command to ensure that important statistics and data records in storage are not permanently lost. As a result of this command, the internal I/O device error counts are stored in the SYS1.LOGREC data set; the SMF buffers are emptied onto one of the SYS1.MANx data sets; and the system log, if still active, is closed and put on the print queue. When these actions are complete, the system issues message IEE334I, stating that the HALT EOD operation was successful.
3.76 TME 10 OPC

Operations planning and control
The TME 10 Operations Planning and Control (TME 10 OPC) Licensed Program is the IBM foundation for enterprise workload management. TME 10 OPC provides a comprehensive set of services for managing and automating the workload. Whether you manage a single-image z/OS system or multi-vendor networks and systems from a single point of control, TME 10 OPC helps you manage and automate the production workload.

TME 10 OPC builds operating plans from your descriptions of the production workload.

TME 10 OPC consists of a base product, the tracker, and a number of features. All the systems in your complex require the base product. The tracker is the link between the system that it runs on and the TME 10 OPC controller.

One z/OS system in your complex is designated the controlling system and runs the controller feature. From this system, you can automatically plan, control, and monitor your entire production workload. Only one controller feature is required, even when you want to start standby controllers on other z/OS systems in a sysplex.

Tivoli OPC makes it possible for the scheduling manager to maintain current and future production processing across your enterprise. Tivoli OPC benefits the scheduling manager by:
- Automatically schedule all production workload activities.
– Automatically resolve the complexity of production workload dependencies and drive the work in the most efficient way.
– Supporting the simulation of future workloads on the system. The scheduler can evaluate, in advance, the effect of changes in production workload volumes or processing resources.
– Giving a real-time view of the status of work as it flows through the system so that the scheduler can quickly:
  • Respond to customer queries about the status of their work.
  • Identify problems in the workload processing.
– Providing facilities for manual intervention.
– Managing many workload problems automatically. The TME 10 OPC production-workload-restart facilities, hot standby, automatic recovery of jobs and started tasks, and data set cleanup provide the scheduler with comprehensive error-and disaster-management facilities.
– Providing a log of changes to the TME 10 OPC production workload data through the audit-trail facility. This assists the scheduler in resolving problems caused by user errors.
– Managing unplannable work.

The operations manager uses the reporting, planning, and control functions to:
– Improve the efficiency of the operation.
– Improve control of service levels and quality.
– Set service level agreements for end-user applications and for services provided.
– Improve relationships with end-user departments.
– Increase the return on your IT investment.
– Develop staff potential.

The Shift Supervisor uses TME 10 OPC, especially in multisystem complexes, where local and remote systems are controlled from a central site. Also it can help the shift supervisor to:
– Monitor and control the flow of production work through multisystem complexes.
– Control the use of mountable devices.
– Separate information about work status from system and other information.
– Provide end users with status information directly.
– Manage the workload if a system failure occurs.
– Make changes to the current plan in response to unplanned events, such as equipment failures, personnel absences, and rush jobs.

The application programmer. The TME 10 OPC user-authority checking enables application development groups to use all the planning and control functions of TME 10 OPC in parallel with—but in isolation from—production systems and services. For the application programmer, it can be a valuable tool for application development staff, enabling them to:
– Package new applications for regular running
– Test new JCL in final packaged form
– Test new applications and changes to existing ones
– Restart or rerun unsuccessful jobs.
The **console operators** can be freed from these time-consuming tasks:
- Starting and stopping started tasks.
- Preparing JCL before job submission.
- Submitting jobs.
- Verifying the sequence of work.
- Reporting job status.
- Performing data set cleanup in recovery and rerun situations.
- Responding to workload failure.
- Preparing the JCL for step-level restarts.

The **workstation operators** gets help in:
- Providing complete and timely status information.
- Providing up-to-date ready lists that prioritize the work flow.
- Providing online assistance in operator instructions.

The **end users** and **help desks** can be informed about the status of workload processing. They can use the ISPF dialogs or the Workload Monitor/2 to check the status of the processing of their applications themselves, from a personal workstation. End users can make queries using the Workload Monitor/2 without having to be familiar with TME 10 OPC, ISPF, or TSO, and without having to be logged on to a local system. The Workload Monitor/2 also provides alerts that can automatically advise end users when their work has completed or ended in error. The help desk can use the Workload Monitor/2 in the same way to answer queries from end users about the progress of their workload processing.
3.77 TME 10 OPC platforms

TME 10 OPC is a state-of-the-art production workload manager, designed to help you meet your present and future data processing challenges. Its scope encompasses your entire enterprise information system, including heterogeneous environments.

Pressures in today's DP environment are making it increasingly difficult to maintain the same level of services to customers. Many installations find that their batch window is shrinking. More critical jobs must be finished before the morning online work begins. Conversely, requirements for the integrated availability of online services during the traditional batch window put pressure on the resources available for processing the production workload. More and more, 7/24 (7 days a week, 24 hours a day) is not only a DP objective but a requirement.

Users and owners of DP services are also making more use of batch services than ever before. The batch workload tends to increase each year at a rate slightly below the increase in the online workload. Combine this with the increase in data usage by batch jobs, and the end result is a significant increase in the volume of work.

Furthermore, there is a shortage of people with the required skills to operate and manage increasingly complex DP environments. The complex interrelationships between production activities—between manual and machine tasks—have become unmanageable without a workload management tool.
TME 10 OPC provides leading-edge solutions to problems in production workload management. It can automate, plan, and control the processing of your enterprise's entire production workload, not just the batch subset. TME 10 OPC functions as an “automatic driver” for your production workload, to maximize the throughput of work and optimize your resources, but it also allows you to intervene manually as required.

When TME 10 OPC interfaces with other system management products, it forms part of an integrated automation and systems management platform for your DP operation.

TME 10 OPC forms operating plans based on user descriptions of the operations department and its production workload. These plans provide the basis for your service level agreements and give you a picture of the production workload at any point in time. You can simulate the effects of changes in your production workload and in resource availability by generating trial plans.

Good planning is the cornerstone of any successful management technique. Effective planning also helps you maximize return on your investments in information technology.

TME 10 OPC automates, monitors, and controls the flow of work through your enterprise's entire DP operation, on both local and remote systems. From a single point of control, TME 10 OPC analyzes the status of the production work and drives the processing of the workload according to installation business policies. It supports a multiple end-user environment, enabling distributed processing and control across sites and departments within your enterprise.
3.78 z/OS OPC configuration

What is a TME 10 OPC Tracker

A tracker is required for every controlled z/OS system in a TME 10 OPC configuration. This includes, for example, local controlled systems within shared DASD or sysplex configurations.

The tracker runs as a z/OS subsystem and interfaces with the operating system (through JES2 or JES3, and SMF), using the subsystem interface and the operating system exits. The tracker monitors and logs the status of work, and passes the status information to the controller via shared DASD, XCF, or ACF/VTAM.

You can exploit the z/OS cross-system Coupling Facility (XCF) to connect your local z/OS systems. Rather than being passed to the controlling system via shared DASD, work status information is passed directly via XCF connections. XCF lets you exploit all of TME 10 OPC's production-workload-restart facilities and its hot standby function.

The tracker on a remote z/OS system passes status information about the production work in progress to the controller on the TME 10 OPC controlling system. All communication between TME 10 OPC subsystems on controlling and remote systems is done via ACF/VTAM.

TME 10 OPC lets you link remote systems using ACF/VTAM networks. Remote systems are frequently used locally “on premises” to reduce the complexity of the DP installation.

Every controlled AS/400® system needs the Tracker Agent for OS/400® feature installed. When this feature is used, status information and job logs for the production workload are...
passed back to the controlling z/OS system using APPC services. The TME 10 OPC controller submits jobs and commands to one system in an AS/400 cluster; from there the work is directed to the target AS/400 system.

Controlled UNIX systems require the OPC Tracker Agent feature for the appropriate implementation of UNIX, including the z/OS Open Edition environment. When one of these features is used, status information and job logs for the production workload are passed back to the controlling z/OS system using TCP/IP services. The TME 10 OPC controller submits jobs and commands directly to the target UNIX system.

If you use Load Leveler to manage workload distribution in your heterogeneous workstation environment, the OPC Tracker Agents for AIX® and the other UNIX implementations can integrate with Load Leveler 1.2.

To control the workgroup workload on OS/2® workstations and servers, you need the Tracker Agent for OS/2® feature. When this feature is used, status information and job logs for the production workload are passed back to the controlling z/OS system using TCP/IP services. The TME 10 OPC controller submits jobs and commands directly to the target workstation system. To control the workgroup workload on Windows® NT® workstations and servers, you need the Tracker Agent for Windows NT® feature. When this feature is used, status information and job logs for the production workload are passed back to the controlling z/OS system using TCP/IP services. The TME 10 OPC controller submits jobs and commands directly to the target workstation system.

Remote systems controlled by other operating environments can also communicate with the TME 10 OPC controller using supplied programs. Although not a full-function tracker agent today, these routines provide you with the opportunity to centralize control and automate the workload on these operating environments. The supplied sample programs demonstrate communication using a variety of methods. The programs can be tailored for a specific environment.

TME 10 OPC Tracker Agents are functionally equivalent to the base z/OS tracker, with the exception that automatic data set cleanup and the job-completion checker (JCC) functions are not provided for non-z/OS platforms. This means you can use TME 10 OPC functions like automatic recovery and automatic job tailoring for your non-z/OS workload. Many installations run business applications on a variety of UNIX platforms. TME 10 OPC provides tracker agents that can manage your workload in several operating system environments. At the time of this writing, tracker agents for OS/400, AIX®/6000, HP-UX, SunOS™, Sun™ Solaris™, Pyramid MIPS ABI, Digital OpenVMS, Digital UNIX, AIX, and System/390® Open Edition operating systems are available, as well as the tracker agents for OS/2 and Windows NT platforms, and the base tracker for z/OS.

What is a TME 10 OPC controller

The controller is the focal point of your TME 10 OPC configuration. It uses the information in the database to determine which jobs to run, when they should run, and where they should run. It contains the controlling functions, the dialogs, and TME 10 OPC’s own batch programs. Only one TME 10 OPC controller is required to control the entire TME 10 OPC installation, including local and remote systems.

The system that the controller is started on is called the TME 10 OPC controlling system. TME 10 OPC systems that communicate with the controlling system are called controlled systems. You need to install in your z/OS system at least one controller for your production systems. It can control the entire TME 10 OPC configuration, both local and remote. You can use the TME 10 OPC controller to provide a single, consistent control point for submitting and tracking the workload on any operating environment.
TME 10 OPC provides open interfaces to let you integrate the planning, scheduling, and control of work units such as online transactions, file transfers, or batch processing in any operating environment that can communicate with z/OS.

**TME 10 OPC as a workload management tool**

TME 10 OPC allows you to:

- Manage your workload on a variety of platforms from a single point of control.
- Run jobs on the right day at the right time.
- Start jobs in the correct order.
- Resolve complex dependencies between jobs.
- Take into account business days and holidays across divisions, states, and countries.
- Provide plans for the future workload to help you manage peak processing (year-end work, for example).
- Optimize hardware resources by allocating work to specific machines.
- Initiate automatic recovery actions in the event of hardware or software failure.
- Maintain logs of work that has run and that is available for viewing or post-processing.
LPA, LNKLST, and authorized libraries

In order to maximize the performance for retrieving executable programs, z/OS has been designed to maintain in memory those executable programs that are needed for fast response to requests coming from z/OS components as well as from the critical applications. Link pack area (LPA), LNKLST, and authorized program facility (APF) libraries described here are the cornerstone of the executable program fetching process. Also the roles of Virtual Lookaside Facility (VLF) and Linklist Lookaside (LLA) components are described at the appropriate level.

Executable programs, whether stored as load modules (coming from a PDS member) or program objects (coming from a PDSE member), must be loaded into both virtual storage and central storage before they can be executed. When one executable program calls another one, either directly by asking for it to be executed or indirectly by requesting a system service that uses it, it does not begin to run instantly. How long it takes before a requested executable program begins to run depends on where in its search order z/OS finds a usable copy, and on how long it takes z/OS to make the copy it finds available.

You should consider these factors when deciding where to place individual executable programs or libraries containing multiple such programs in the system-wide search order:

- The search order z/OS uses for executable programs
- How placement affects virtual storage boundaries
- How placement affects system performance
- How placement affects application performance
4.1 The creation of an executable program

The first step in creating an executable program is to write the source code. This can be done using a high level language compiler such as Cobol, PL/1, C, or using the assembler usually referred to as high level assembler. The output of the compiler or the assembler is called an object module. The source statements are already converted to machine instructions, but such code is not ready to be executed.

The second step is to process the object module by a z/OS utility program called the Binder. The Binder, following information contained in the object module, creates an executable program. If required, the binder links the module with other object modules, and also resolves relative address references between object modules. The format and the name of the Binder's output, the executable program, depends on the type of library used to store the program, as follows:

- Load module, if stored in a PDS
- Program object, if stored in a PDSE

IBM recommends, in general, using PDSEs instead of a PDS. Program object format has several advantages when compared with load modules, and PDSEs are more flexible and efficient than a PDS.

In this chapter and in many manuals the expression “executable program” is translated into load module even if the code is stored in a PDSE. Here, we use the expression “program object” only when we need to make a remark about that specific type of executable program.
The last step is to load or fetch the executable program into virtual and central storage. This task is done by the a z/OS program named Loader, which belongs to the z/OS program management component. During the load, some address variables are finally resolved by adding to them the virtual address where they are loaded.

**Program execution considerations**

One variation of this process is during testing the logic of the code, to use the batch loader where the executable program is stored directly into virtual storage and is then ready to be executed.

If the language that you selected is interpretative, such as Java™, the picture is different. There is no compilation and the running program is the Java interpreter, also called JVM™. It reads the Java source and translates it into machine code, and then executes the machine instructions. When a CPU gets control back, it translates the next source statement and so on.
4.2 Link pack area (LPA)

The link pack area (LPA) is a common non-getmainable virtual storage area. It is built at IPL time by the load of load modules contained in SYS1.LPALIB and its concatenations. There are two LPAs (one above and another below the 16-M line) depending on the residence mode of the load module. Because the load modules are in the common area they are shared by all address spaces in the system. The load modules must be refreshable, meaning that they are not self-modifying. In this context, a reentrant load module means that it can be executed concurrently by several tasks but it cannot be temporarily modified. Then, each copy can be used by any number of tasks running in any number of CPUs in any number of address spaces at the same time. Modules found in LPA do not need to be brought into virtual storage on request because they are already in virtual storage. The benefit of having lots of load modules in LPA is that it decreases the use of the private areas.

FLPA and central storage
Modules placed anywhere in LPA are always in virtual storage and sometimes in central storage. Observe that the load module page that contains the instructions in execution must be in a central storage frame. Whether modules in LPA are in central storage depends on how often they are used by all the users of the system, and on how much central storage is available. The more often an LPA module is used, and the more central storage is available on the system, the more likely it is that the pages containing the copy of the module are in central storage at any given time, without suffering page faults. When all the pages containing an LPA module (or its first page) are not in central storage when the module is called, the module begins to run only after its first page has been brought into central storage.
LPA pages can be stolen but never paged out because there are always valid copies in the LPA page data set (loaded at IPL time). Recall that LPA pages are not altered.

Many z/OS components’ code is loaded in PLPA, such as: SVC type 3 and 4 routines, access methods (VSAM and QSAM), initiators, and JES load modules.

**Modules in CSA**

Modules can also be loaded into CSA by authorized programs. An example of this is the implementation of dynamic LPA, where after an IPL, new load modules are added to LPA. Because the borders of LPA cannot be modified and CSA is a getmainable common virtual storage area, the new load modules are fetched into CSA. When modules are loaded into CSA and shared by multiple address spaces, the performance considerations are similar to those for modules placed in LPA. There are pieces of CSA that are pageable and pieces of CSA that are fixed depending on the subpool number used during a getmain of the storage area.
4.3 LPA subareas

Subareas of LPA

The link pack area is a section of the common area of an address space. It exists below the system queue area (SQA) and consists of the pageable link pack area (PLPA), then the fixed link pack area (FLPA) if one exists, and finally the modified link pack area (MLPA).

For more information, see z/OS MVS Initialization and Tuning Reference, SA22-7592.

Figure 4-3 shows a partial list of PLPA load modules.

Each component of LPA has a counterpart in the extended common area (that is, above the 16 megabyte line) as follows:

**FLPA**
For integrity reasons there are z/OS functions that cannot suffer a page fault. If this function is implemented through LPA load modules, these load modules’ pages must be page fixed (no page steals). At IPL time, the installation may declare those load modules’ names, in the IEAFIXxx parmlib member, and the IPL process loads them in the fixed link pack area (FLPA), which is a non pageable area of storage. The FLPA exists only for the duration of an IPL. Therefore, if an FLPA is desired, the modules in the FLPA must be specified for each IPL (including quick-start and warm-start IPLs).

Modules placed in the FLPA must be refreshable, that means they are never altered during execution.
It is the responsibility of the installation to determine which modules, if any, to place in the FLPA. Note that if a module is heavily used and is in PLPA, the system’s paging algorithms will tend to keep that module in central storage.

**PLPA**

During an IPL, if the CLPA option is on, the SYS1.LPALIB member and its concatenated data sets, as defined in the LPALSTxx parmlib member, are copied into the PLPA page data set and consequently into virtual storage.

In the PLPA page data set, ASM maintains records that have pointers to the PLPA and extended PLPA pages (above 16 M). During quick-start or warm-start IPLs, the system uses the pointers to locate the PLPA and extended PLPA pages. The system then rebuilds the PLPA and extended PLPA page tables, and uses them for the current IPL.

If CLPA is specified at the operator console during the IPL, indicating a cold start is to be performed, the PLPA storage is deleted and made available for system paging use. A new PLPA and extended PLPA are then loaded, and pointers to the PLPA and extended PLPA pages are recorded in the PLPA page data set.

**MLPA**

This LPA area may be used to contain reentrant load modules from APF-authorized libraries that are part of the PLPA during the current IPL. The MLPA exists only for the duration of an IPL. Therefore, if an MLPA is desired, the modules in the MLPA must be specified in the IEALPAXx parmlib member for each IPL, including quick-start and warm-start IPLs. MLPA is allocated just below the FLPA, or the PLPA if there is no FLPA. The extended MLPA is allocated above the extended FLPA, or the extended PLPA if there is no extended FLPA. When the system searches for a load module, MLPA is searched before PLPA.

*Note:* The MLPA can be used at IPL time to temporarily modify or update the PLPA with new or replacement modules. No actual modification is made to the quick start PLPA stored in the system’s paging data sets. The MLPA is read-only, unless NOPROT is specified on the MLPA system parameter.
### 4.4 Pageable link pack area (PLPA)

The PLPA is an area of common storage that is loaded at IPL time (when you do a cold start, specify CLPA in your IPL).

This area contains SVC routines, access methods, and other read-only system programs, along with any read-only reenterable user programs selected by an installation that can be shared among users of the system. It is also desirable to place all frequently used refreshable SYS1.LINKLIB and SYS1.CMDLIB modules in the PLPA.

#### Load modules AMODE and RMODE

A program module has a residence mode, RMODE, assigned to it, and each entry point and alias has an addressing mode, AMODE, assigned to it. You can specify one or both of these modes when creating a program module or you can allow the binder to assign default values.

#### Contents of the PLPA or extended PLPA

The PLPA and extended PLPA contain all members of SYS1.LPALIB and any other libraries that are specified in the active LPALSTxx through the LPA parameter in the IEFASYSxx or from the operator’s console at system initialization. The modules in the PLPA or extended PLPA must be refreshable. Load modules are placed in the PLPA or extended PLPA, depending on the RMODE of these load modules. Load modules with an RMODE of 24 are placed in the PLPA, while those with an RMODE of ANY are placed in the extended PLPA.
4.5 LPA parmlib definitions

- **LPALSTxx parmlib member specification**

  LPA = {aa} {aa,bb,...[,L]}

  (YEASYSxx parameter)

- **Operator can override parmlib specification**

  IEA101A SPECIFY SYSTEM PARAMETERS FOR OS/390 02.07.00 HBB6607
  R 00,LPA=03
  IEE600I REPLY TO 00 IS;LPA=03

*Figure 4-5  LPA parmlib definitions*

**Specifying LPA parameters in parmlib**

The two characters (A through Z, 0 through 9, @, #, or $) represented by aa (or bb and so forth) in Figure 4-5 are appended to LPALST to form the name of the LPALSTxx parmlib members.

If the L option is specified, the system displays the contents of the LPALSTxx parmlib members at the operator's console as the system processes the members.

The LPA parameter is only effective during cold starts, or during IPLs in which you specify the CLPA option. The LPA parameter does not apply to modules requested through the MLPA option.

An example of overriding the value of the LPA parameter in the IEASYSxx during system initialization is as follows:

IEA101A SPECIFY SYSTEM PARAMETERS FOR z/OS 02.05.00 HBB6605
r 00,LPA=03
IEE600I REPLY TO 00 IS;LPA=03

LPALST03 was selected during system initialization.
How to specify modules in the PLPA or extended PLPA

Use one or more LPALSTxx members in the SYS1.PARMLIB to concatenate your installation's program library data sets to SYS1.LPALIB. You can also use the LPALSTxx member to add your installation's read-only reenterable user programs to the pageable link pack area (PLPA). The system uses this concatenation, which is referred to as the LPALST concatenation, to build PLPA. The word “library” commonly used in z/OS manuals means a PDS or a PDSE data set organization used to contain executable programs.

**Note:** The system does not check user catalogs when it searches for data sets to be added to the LPALST concatenation. Therefore, the data sets in the concatenation must be cataloged in the system master catalog.

During nucleus initializing process (NIP), the system opens and concatenates each data set specified in LPALSTxx in the order in which the data set names are listed, starting with the first-specified LPALSTxx member.

If one or more LPALSTxx members exist, and the system can open the specified data sets successfully, the system uses the LPALST concatenation to build the PLPA (during cold starts and IPLs that included the CLPA option). Otherwise, the system builds the PLPA from only those modules named in the SYS1.LPALIB.

**Note:** The LPALST concatenation can have up to 255 extents. If you specify more data sets than the concatenation can contain, the system truncates the LPALST concatenation and issues messages that indicate which data sets are excluded in the concatenation.
4.6 Coding a LPALSTxx parmlib member

Some important syntax rules for the creation of LPALSTxx are:

- On each record, place a string of data set names separated by commas.
- If a data set is not cataloged in the system master catalog, but is cataloged in a user catalog, specify in parentheses immediately following the data set name the one to six character VOLSER of the pack on which the data set resides.
- Indicate continuation by placing a comma followed by at least one blank after the last data set name on a record.
4.7 Fixed link pack area

Figure 4-7  Fixed link pack area

**Fixed link pack area (FLPA or extended FLPA)**

The FLPA is loaded at IPL time, with the load modules listed in the active IEAFIXxx member of SYS1.PARMLIB. These load modules must be kept in fixed storage frames (that is, they cannot be paged out).

This area should be used only for load modules that should not allow page faults because of integrity considerations. Modules placed in the FLPA must be reentrant and refreshable.

**Contents of the FLPA or extended FLPA**

Load modules from the LPALST concatenation, the LNKLST concatenation, SYS1.MIGLIB, and SYS1.SVCLIB can be included in the FLPA. FLPA is selected through specification of the FIX parameter in IEASYSxx, which is appended to IEAFIX to form the IEAFIXxx parmlib member, or from the operator's console at system initialization.

Load modules specified in IEAFIXxx are placed in the FLPA or extended FLPA, depending on the RMODE of these load modules: load modules with an RMODE of 24 are placed in the FLPA, while those with an RMODE of ANY are placed in the extended FLPA.
4.8 Coding the IEAFIXxx member

Specify - (INCLUDE - LIBRARY - MODULES)

- Consider module order
  - Saves search time

Figure 4-8 The IEAFIXxx parmlib member

### Specifying modules in the FLPA or extended FLPA

Figure 4-8 shows an example of IEAFIXxx parmlib member. Use the IEAFIXxx member in SYS1.PARMLIB to specify the names of the load modules that are to be fixed in central storage for the duration of an IPL. Load modules specified in IEAFIXxx are loaded and fixed in the order in which they are specified in the member. To keep search time within reasonable limits, do not allow the FLPA to become excessively large. For more information, see z/OS MVS Initialization and Tuning Reference, SA22-7592.

**Note:** These libraries should be cataloged in the system master catalog.

### Coding IEAFIXxx in SYS1.PARMLIB

The statements or parameters used in IEAFIXxx are:

- **INCLUDE**
  - Specifies load modules to be loaded as temporary extensions to the existing pageable link pack area (PLPA).

- **LIBRARY**
  - Specifies a qualified data set name. The specified library must be cataloged in the system master catalog.

- **MODULES**
  - Specifies a list of 1 to 8 character load module names.

**Note:** The advantage of using the FLPA is the reduction in the central storage available for paging old jobs and starting new jobs. Remember that pages referenced frequently tend to remain in central storage even when they are not fixed.
4.9 Specifying the IEAFIXxx member

- Operator response to IEA101A - system parameters
  - R 00,FIX=aa       - (overrides IEASYSxx FIX=)
- Display contents of IEAFIXxx on console
  - Use L option
- Override the page protection default
  - Use NOPROT option

```plaintext
FIX= {aa}
{ (aa, [,L] [,NOPROT]) }
{ (aa,bb,...[,L] [,NOPROT]) }
```

**Figure 4-9  Specifying the IEAFIXxx parmlib member**

**How to specify FIX parameter during system initialization**

The two characters (A through Z, 0 through 9, @, #, or $) represented by aa (or bb and so forth), are appended to IEAFIX to form the name of the IEAFIXxx parmlib members. The options are:

- **L**
  - If the L option is specified, z/OS displays the contents of IEAFIXxx parmlib members at the operator’s console as the system processes the members.

- **NOPROT**
  - By default, the LPA load modules in the IEAFIXxx parmlib members are page-protected in storage. It means that the protection key in central storage is B’0000’ (four zero-bits), and usually the PSW key is B’1000’; you have a protection exception when altering the code. However, the NOPROT option allows an installation to override the page protection default.

**Syntax format for FIX parameter:** FIX= {aa} {(aa,[,L],[,NOPROT])} {(aa,bb,...[,L],[,NOPROT])}

An example of overriding the value of the FIX parameter that was specified in the IEASYSxx during system initialization follows. Member 01 is selected during system initialization:

```
IEA101A SPECIFY SYSTEM PARAMETERS FOR z/OS 02.05.00 HBB6605
R 00,FIX=01
IEE600I REPLY TO 00 IS;FIX=01
```
4.10 Modified link pack area (MLPA)

Modified link pack area (MLPA/extended MLPA)

This area can be used to contain reenterable load modules from APF-authorized libraries (refer to “Authorized program facility (APF)” on page 283) that are to be part of the pageable extension to the link pack area during the current IPL.

The MLPA exists only for the duration of the IPL. Therefore, if an MLPA is desired, the load modules in the MLPA must be specified for each IPL (including quick start and warm start IPLs).

Contents of the MLPA or extended MLPA

MLPA contains load modules listed in the active IEALPAxx member of SYS1.PARMLIB, through the specification of the MLPA parameter in the IASYSxx or from the operator's console at system initialization.

LPA load modules specified in the IEALPAxx are placed in the MLPA or the extended MLPA, depending on the RMODE of the load modules: Load modules with an RMODE of 24 are placed in the MLPA, while those with an RMODE of ANY are placed in the extended MLPA.
4.11 Coding the IEALPAxx member

Specify - (INCLUDE - LIBRARY - MODULES)

**Figure 4-11  Coding the IEALPAxx parmlib member**

**How to code IEALPAxx member of the SYS1.PARMLIB**

Figure 4-11 is an example of the IEALPAxx parmlib member. Use the IEALPAxx member to specify the reenterable modules that are to be added as a temporary extension to the pageable link pack area (PLPA). The modules are cataloged in the system master catalog.

This extension is temporary because the modules will remain in paging data sets and will be listed on the active LPA queue only for the duration of the IPL.

The system will not automatically quick-start or warm-start these modules (that is, reinstate the modules without re-specification of the MLPA parameter). Both the modified LPA (MLPA) and the fixed LPA (FLPA) modules (those named in IEAFIXxx) do not require the system to search the LPA directory when one of the modules is requested. The modified LPA, unlike the fixed LPA, however, contains pageable modules that behave in most respects like PLPA modules.

**Note:** A library that includes modules for the MLPA must be a PDS. You cannot use PDSEs in the LPALST concatenation.

The data sets in the LPALST can be a mixture of APF-authorized and non-APF-authorized data sets. However, any module in the modified link pack area will be treated by the system as though it came from an APF-authorized library. Ensure that you have properly protected any library that contributes modules to the modified link pack area to avoid system security and integrity exposures, just as you would protect any APF-authorized library.
You can use IEALPAxx to temporarily add or replace SVC or ERP routines. Another possible application would be the testing of replacement LPA modules that have been altered by PTFs.

LPA modules specified in IEALPAxx are placed in the MLPA or in the extended MLPA, based on the RMODE of the modules: modules with an RMODE of 24 are placed in the MLPA, while those with an RMODE of ANY are placed in the extended MLPA. By default, the MLPA and the extended MLPA are page protected, which means that a protection exception will occur if there is an attempt to store data into either area. To override page protection, use the NOPROT option on the MLPA system parameter.

LPA modules that have been replaced through IEALPAxx are not physically removed from the PLPA or from the LPA directory. They are, however, logically replaced because, when one of them is requested, MLPA is searched first and the system does not examine the LPA directory that contains the name of the replaced module.

The system searches the fixed LPA before the modified LPA for a particular module and selects the module from the modified LPA only if the module is not also in the fixed LPA.
4.12 Specifying the IEALPArxx member

Operator response to IEA101A - system parameters

- R 00,MLPA=02    - (overrides IEASYSxx MLPA=)

Display contents of IEALPArxx on console

- Use L option

Override the page protection default

- Use NOPROT option

MLPA= {aa

{ (aa,[,L][,NOPROT])

{ (aa,bb,...[,L][,NOPROT]) }

Figure 4-12 Specifying the IEALPArxx member

Specifying the MLPA member at system initialization

The two characters (A through Z, 0 through 9, @, #, or $) represented by aa (or bb and so forth), are appended to IEALPA to form the name of the IEALPArxx parmlib members. The options are:

L            If the L option is specified, the system displays the contents of the IEALPArxx parmlib members at the operator's console as the system processes the members.

NOPROT       By default, the LPA load modules in the IEALPArxx parmlib members are page-protected in storage. However, the NOPROT option allows an installation to override the page protection default.

Syntax format for MLPA parameter: MLPA= {aa

{(aa,[,L][,NOPROT]) 

{(aa,bb,...[,L][,NOPROT])}}

An example of overriding the value of the MLPA parameter in the IEASYSxx during system initialization follows; IEALPA02 was selected during system initialization:

IEA101A SPECIFY SYSTEM PARAMETERS FOR z/OS 02.05.00 HBB6605
R 00,MLPA=02
1EE6001 REPLY TO 00 IS;MLPA=02

266   ABCs of z/OS System Programming Volume 2
4.13 Dynamic LPA functions

- LPA statement in PROGxx parmlib member
  - LPA ADD
  - LPA DELETE
  - LPA CSAMIN

- SETPROG LPA operator command

- D PROG,LPA operator command

- CSVDYLPA macro

Managing dynamic LPA content
Dynamic link pack area has the ability to dynamically add or delete load modules from the link pack area (LPA) after the IPL. This allows optional and new products to be loaded into the system without requiring an IPL. It also enables you to display load modules residing in LPA.

A load module added dynamically is found before one of the same name added during the IPL. This allows you to test new load modules before you put them into production. Load modules added dynamically to the LPA are loaded into the common area (CSA) or extended common area (ECSA). The parameter CSAMIN guarantees a minimum value of free CSA after the load of the PLPA load module; if this is not honored the load fails.

How to perform dynamic LPA functions
The dynamic LPA functions can be invoked in one of the following ways:

- The PROGxx parmlib member includes the LPA statements, which are used to define what load modules can be added to or deleted from LPA after the IPL. You use the SET command to execute the functions described in the PROGxx parmlib member; for example, SET PROG=xx.
- The SETPROG LPA command can be used to initiate a change (add or delete) to the LPA.
- The DISPLAY PROG,LPA command can be used to display information about load modules that have been added to LPA.
- The CSVDYLPA macro allows an authorized program to initiate dynamic LPA services.

For more information, see z/OS MVS Initialization and Tuning Reference, SA22-7592.
Overview of the LNKLST

Program management is a z/OS component that deals with load modules. Here, you see how we can improve the performance of program management by using LNKLST and mechanisms utilized to locate and fetch load modules, such as LLA and VLF.

Initially, we can say that LNKLST allows the installation to concatenate load module libraries (PDS or PDSE) with the SYS1.LINKLIB. Concatenation means that the access method processes all the concatenated data sets as if they were other extents of the first data set, that is, a continuation and not a different data set.

LLA is a program management z/OS component that keeps in virtual storage directory entries from load module libraries, thereby speeding up the fetch of a load module. VLF is another z/OS component that keeps objects in virtual storage in order to save I/O operations that would load such objects. One of these object types is load modules.

When determining which data sets LLA and VLF are to manage, try to limit the choices to production load libraries that are rarely changed. This avoids a refresh of LLA or VLF operations. Because LLA manages LNKLST libraries by default, you need only determine which non-LNKLST libraries LLA is to manage. If, for some reason, you do not want LLA to manage particular LNKLST libraries, you must explicitly remove such libraries from LLA management.

To obtain the most performance benefit, you should plan to use both LLA and VLF. This reduces the I/O required to find directory entries and to fetch load modules from DASD.
Selected load modules can be staged in VLF dataspaces. LLA does not use VLF to manage library directories. When used without VLF, LLA eliminates only the I/O the system would use in searching library directories on DASD.

All LLA-managed libraries must be cataloged. This includes LNKLST libraries. A library must remain cataloged for the entire time it is managed by LLA. The benefits of LLA apply only to load modules that are retrieved through the following macros: LINK, LINKX, LOAD, ATTACH, ATTACHX, XCTL, and XCTLX. These macros are issued by a load module running under a task in order to load another load module. For example, the initiator attaches the load module name described in the EXEC PGM card in order to start a step task. The LNKLST is a group of system and user-defined load libraries that is a continuation of SYS1.LINKLIB and also indicates the search order the system uses for programs.

Executable programs, whether stored as load modules (PDS) or program objects (PDSE), must be loaded into both virtual storage and central storage before they can be executed.

By default, the LNKLST begins with these system data sets:

- SYS1.LINKLIB
- SYS1.MIGLIB
- SYS1.CSSLIB

The LNKLST concatenation

You can change this order and add other load libraries to the LNKLST concatenation. The LNKLST concatenation is established at IPL time and can optionally be modified dynamically. It consists of SYS1.LINKLIB, followed by the libraries specified in one or more LNKLSTxx members of SYS1.PARMLIB. The LNKLSTxx member is selected through the LNK parameter in the IEASYSxx member of SYS1.PARMLIB.

The building of the LNKLST concatenation happens during an early stage in the IPL process, before any user catalogs are accessible, so only those data sets whose catalog entries are in the system master catalog can be included in the linklist. To include in the LNKLST a data set that is cataloged in a user catalog, you have to specify both the name of the data set and the volume serial number (VOLSER) of the DASD volume on which the data set resides.

Note: The number of data sets that you can concatenate to form the LNKLST concatenation is limited by the total number of DASD extents the data sets will occupy. The total number of extents must not exceed 255. When the limit has been exceeded, the system writes error message IEA328E to the operator's console.

These data sets are concatenated in the order in which they appear in the LNKLSTxx members, and the system creates a data extent block (DEB) describing the data sets concatenated to SYS1.LINKLIB and their extents. The DEB contains details of each physical extent allocated. These extents remain for the duration of the IPL. After the LNKLST process, LLA starts managing the LNKLST data sets and can be used to control updates to them.

Specifying the LNK parameter

An example of overriding the value of LNK parameter in IEASYSxx along IPL follows:

```
IEA101A SPECIFY SYSTEM PARAMETERS FOR z/OS 02.05.00 HBB6605
R 00, LNK=03
IEE6001I REPLY TO 00 IS; LNK=03
```

For more information, see z/OS MVS Initialization and Tuning Reference, SA22-7592, and z/OS MVS System Commands, SA22-7627.
4.15 Dynamic LNKLST functions

- LNKLST statement in PROGxx parmlib member
  - SET PROG=xx command
- SETPROG LNKLST operator command
- D PROG, LNKLST operator command
- CSVDYNL macro

Managing dynamic LNKLST content
You can change the current LNKLST set dynamically through the SET PROG=xx and SETPROG LNKLST commands. In reality, you do not change a LNKLST, you replace the full LNKLST.

A LNKLST set remains allocated until there are no longer any jobs or address spaces associated with its libraries. If the current LNKLST set is dynamically changed, any job or address space associated with a previous LNKLST set continues to use the data sets until the job or address space finishes. Thus, a previously current LNKLST set might be active or in use by a job or address space even though a new current LNKLST set has been activated. Jobs or address spaces started after a new current LNKLST set is activated use this set.

The SET PROG=xx and SETPROG LNKLST commands remove the definition of a LNKLST set from z/OS, associate a job or address space with the current LNKLST set, and locate a specific load module associated with a data set in LNKLST set. You can update the set content dynamically, as follows:

- You can create a PROGxx parmlib member with the new changes to the LNKLST set, then issue the SET PROG=xx operator command to activate the changes.
- You can simply use the SETPROG LNKLST operator command to update the LNKLST directly.
- You can use the D PROG, LNKLST command to display information about the LNKLST set.
- Finally, you can use the CSVDYNL macro programming service in an authorized program to change the LNKLST concatenation for associated jobs and address spaces.
4.16 Library lookaside (LLA)

The library lookaside (LLA) overview
Library lookaside (LLA) is a z/OS function implemented in an address space that maintains in the private area a copy of the directory entries of the libraries that it manages. Since the entries are cached, the system does not need to read the data set directory entries to find out where a load module is stored before fetching it from DASD. This greatly reduces I/O operations.

The main purpose of using LLA is to improve the performance of load module directory searching on your system. On top of that, LLA could be a user of VLF facilities to keep copies of load modules in VLF data spaces.

How LLA improves performance
LLA improves load module fetch performance in the following ways:

1. By maintaining (in the LLA address space) copies of the library directories, program management uses this to locate load modules. Program management can quickly search the LLA copy of a directory in virtual storage instead of using costly I/O to search the PDS directories on DASD.

2. By placing (or staging) copies of selected load modules in a virtual lookaside facility (VLF) dataspace named DCSVLLA when you define the LLA class to VLF, and start VLF. The system can quickly fetch load modules from virtual storage, rather than using slower I/O to fetch the load modules from the DASD libraries.
3. By determining which load modules, if VLF staged, would provide the most benefit to load module fetch performance. LLA evaluates load modules as candidates for staging based on statistics it collects about the members of the libraries it manages such as load module size, frequency of fetches per load module (fetch count), and the time required to fetch a particular load module. If necessary, you can directly influence LLA staging decisions through installation exit routines CSVLLIX1 and CSVLLIX2.

**LLA-managed libraries**

By default, LLA address space caches directory entries for all the load modules in the data sets included in the linklist concatenation defined in either the LNKLSTxx or PROGxx parmlib members.

You can also identify other user-defined load libraries that contain frequently used load modules to be managed by LLA.

The big problem of caching in order to boost performance is the possibility that the data kept in the virtual storage buffers to avoid I/O operations might be out of date because of updates done in the DASD data set. LLA can avoid that through the option GET_LIB_ENQ (YES) in the CSVLLAxx parmlib member or by the installation F LLAREFRESH command. Refer to “CSVLLAxx SYS1.PARMLIB member” on page 273 for more information.

**Planning LLA use**

Before you can use LLA, you have to do the following:

1. Determine which libraries should be LLA-managed libraries.
2. Code the CSVLLAxx parmlib member to include, modify, and remove the LLA-managed libraries as well as to optimize the performance of the search processing and selectively refresh LLA directory entries.
3. Learn how to control the LLA through the operator commands START, STOP, and MODIFY LLA. LLA directory entries can be selectively refreshed via the operator command F LLAREFRESH. Refer to the next topic for more about the refresh concept.
4.17 CSVLLAxx SYS1.PARMLIB member

You use the CSVLLAxx parmlib member to specify which libraries, in addition to the LNKLST concatenation, library lookaside is to manage.

You can also use CSVLLAxx to specify:

- Libraries to be added or removed from LLA management while LLA is active.
- Whether LLA is to hold an enqueue for the libraries it manages. If you specify `GET_LIB_ENQ(YES)`, which is the default, LLA obtains a shared enqueue for the libraries it manages. The shared enqueue allows your job to read the libraries, but not to move or erase them. To update these libraries, you must first remove them from LLA management through the REMOVE keyword. This function guarantees data integrity.
- Use a FREEZE|NOFREEZE option per library. The NOFREEZE option prevents directory entries being kept in the LLA address space, so no performance improvements are achieved for directory access. The reason may be that lots of updates are done in the library.
- Members of libraries, or whole libraries, to be selectively refreshed in the LLA directory.

```
LIBRARIES(libname1,libname2,[-LNKLST-],...)
MEMBERS(mmbr1,mmbr2,...)
LNKMEMBERS(mmbr1,mmbr2,...)
REMOVE(libname1,libname2,[-LNKLST-],...)
GET_LIB_ENQ(YES|NO)
PARMLIB(dsn) SUFFIX(xx)
FREEZE(libname1,libname2,[-LNKLST-],...)
NOFREEZE(libname1,libname2,[-LNKLST-],...)
EXIT1(ON|OFF)
EXIT2(ON|OFF)
PARMSUFFIX(xx)
```

START LLA,LLA=xx
MODIFY LLA,UPDATE=xx
MODIFY LLA,REFRESH

Figure 4-17 CSVLLAxx parmlib member

CSVLLAxx parmlib member

You use the CSVLLAxx parmlib member to specify which libraries, in addition to the LNKLST concatenation, library lookaside is to manage.

**Note:** If you do not supply a CSVLLAxx member, LLA by default manages the directories only of those libraries defined in the LNKLST concatenation.

You can also use CSVLLAxx to specify:

- Libraries to be added or removed from LLA management while LLA is active.
- Whether LLA is to hold an enqueue for the libraries it manages. If you specify `GET_LIB_ENQ(YES)`, which is the default, LLA obtains a shared enqueue for the libraries it manages. The shared enqueue allows your job to read the libraries, but not to move or erase them. To update these libraries, you must first remove them from LLA management through the REMOVE keyword. This function guarantees data integrity.
- Use a FREEZE|NOFREEZE option per library. The NOFREEZE option prevents directory entries being kept in the LLA address space, so no performance improvements are achieved for directory access. The reason may be that lots of updates are done in the library.
- Members of libraries, or whole libraries, to be selectively refreshed in the LLA directory.

```
LIBRARIES(libname1,libname2,[-LNKLST-],...)
MEMBERS(mmbr1,mmbr2,...)
LNKMEMBERS(mmbr1,mmbr2,...)
REMOVE(libname1,libname2,[-LNKLST-],...)
GET_LIB_ENQ(YES|NO)
PARMLIB(dsn) SUFFIX(xx)
FREEZE(libname1,libname2,[-LNKLST-],...)
NOFREEZE(libname1,libname2,[-LNKLST-],...)
EXIT1(ON|OFF)
EXIT2(ON|OFF)
PARMSUFFIX(xx)
```

START LLA,LLA=xx
MODIFY LLA,UPDATE=xx
MODIFY LLA,REFRESH
Additional CSVLLAxx members to be used to control LLA processing. These members can reside in data sets other than SYS1.PARMLIB.

Whether exit routines are to be called during LLA processing.

For more information, see z/OS MVS Initialization and Tuning Reference, SA22-7592.

**How to start and stop LLA**

To start LLA, use the `START LLA,LLA=xx` command. This command identifies the CSVLLAxx parmlib member to be used to build the LLA directory. This command is issued during system initialization by the IBM-supplied IEACMD00 parmlib member; the command can also be entered by the operator.

The parameters for the `S LLA` command are:

- **LLA** - Invokes the LLA procedure and creates the LLA address space.
- **LLA=xx** - Indicates which CSVLLAxx parmlib member LLA is to use. If you omit LLA=xx, LLA will build its directory using only the LNKLST libraries.
- **SUB=MSTR** - Indicates that the name of the subsystem that will process the task is the master subsystem. If you omit this parameter, the JES subsystem starts LLA. The resulting dependency on JES requires LLA to be stopped when stopping JES.

To stop LLA, use the `P LLA` operator command.

The parameter for the `P LLA` command is:

- **LLA** - The job name assigned to the LLA address space.

For more information, see z/OS MVS Initialization and Tuning Reference, SA22-7592, and z/OS MVS System Commands, SA22-7627.

**How to refresh LLA**

Caching in order to boost performance may cause integrity problems because the data kept in the virtual storage buffers to avoid I/O operations could be out of date because of updates done in the DASD data set. LLA accepts an installation command refresh that can refresh totally all the libraries managed by LLA, which is bad for performance, or a selective member refresh, which is recommended. You can use the `MODIFY LLA` command to change LLA dynamically, in one of the following ways:

- **MODIFY LLA,REFRESH**
  
  This command rebuilds LLA’s directory for the entire set of libraries managed by LLA. This action is often called the complete refresh of LLA.
Chapter 4. LPA, LNKLST, and authorized libraries

MODIFY LLA, UPDATE=xx

This command rebuilds LLA’s directory only for specified libraries or load modules. xx identifies the CSVLLAxx member that contains the names of the libraries for which directory information is to be refreshed. This action is often called a selective refresh of LLA.

If the library is shared by several z/OS systems, as in a Parallel Sysplex, the Modify LLA command must be issued in all systems.

Note: There are several situations where you need to refresh the LLA with the latest version of the directory information from the DASD. Whenever you update a load module in a library that LLA manages, make sure you follow the update by issuing the appropriate form of the F LLA command. Otherwise, LLA continues to use an older version of a load module. If you delete a data set from the current LNKLST set, LLA continues working, and continues finding load modules in the deleted library! This is because the physical addresses of the members are still held by LLA even though it is no longer possible to open the directory. This only works, of course, until the physical space on the DASD is reused by something else. You also find yourself in the situation where you need to compress a data set from the LNKLST set. You should refresh LLA’s cache after the compress. Otherwise, the directory entries in the LLA for every load module moved during the compress process would be invalid. This could lead to abends whenever a user attempts to load one of these modules until a refresh is done.

Use the following to do a complete update of the LLA:

F LLA, REFRESH
CSV210I LIBRARY LOOKASIDE REFRESHED
4.18 Compressing LLA-managed libraries

- Issue a MODIFY LLA,UPDATE=xx command
  - CSVLLAxx parmlib member has a REMOVE statement identifying the library that needs to be compressed
- Compress the library
- Issue a MODIFY LLA,UPDATE=xx command
  - CSVLLAxx parmlib member includes a LIBRARIES statement to return the compressed library to LLA management

**How to compress LLA-managed libraries**

Observe that a PDS library sometimes needs to be compressed to reclaim the free space caused by member deletions. The recommended procedure for compressing an LLA-managed library is:

1. Create a new CSVLLAxx member that includes a REMOVE statement identifying the library that needs to be compressed.

```
Menu Utilities Compilers Help
----------------------------------------------
BROWSE SYS1.PARMLIB(CSVLLA02) - 01.01 Line 00000000 Col 001 080
*********************************** Top of Data ***********************************
REMOVE(SYS1.PRODLIB)
*********************************** Bottom of Data ***********************************
```

Then issue the `F LLA,UPDATE=xx` command, as follows:

```
F LLA,UPDATE=02
IEE252I MEMBER CSVLLA02 FOUND IN SYS1.PARMLIB
CSV210I LIBRARY LOOKASIDE UPDATED
```

2. Compress the library.
There are two ways of compressing a data set:

- You can issue the line command **Z** against the data set you want to compress from the ISPF panel.

  ![ISPF panel screenshot]

- Or you can submit a job to compress the data set using the utility **IEBCOPY** as shown in the following sample JCL.

```plaintext
//COMPRES JOB (),'MVSSP',NOTIFY=&SYSUID,CLASS=A,MSGLEVEL=(1,1),
MSGCLASS=X

//*******************************************
//            COMPRESSING DATA SETS USING IEBCOPY
//*******************************************

//STEP1 EXEC PGM=IEBCOPY
//SYSPRINT DD SYSOUT=* 
//INPUT DD DSNAME=SYS1.LINKLIB,DISP=SHR 
//OUTPUT DD DSNAME=SYS1.LINKLIB,DISP=SHR 
//SYSIN DD * 
COPY INDD=INPUT,OUTDD=OUTPUT 
```

3. Create a new CSVLLAxx member that includes a **LIBRARIES** statement to return the compressed library to LLA management.

![CSVLLA03 parmlib member]

Then issue the **F LLA,UPDATE=xx** command, as follows:

```plaintext
F LLA,UPDATE=03  
IEE252I MEMBER CSVLLA03 FOUND IN SYS1.PARMLIB 
CSV210I LIBRARY LOOKASIDE UPDATED 
```
Virtual lookaside facility (VLF) overview

The virtual lookaside facility (VLF) is a z/OS component that enables an authorized program, a VLF exploiter, to store named data objects in dataspaces managed by VLF and to retrieve these objects by name on behalf of users in multiple address spaces. VLF is designed primarily to improve performance by retrieving the most frequently used objects from virtual storage rather than performing repetitive I/O operations from DASD. VLF runs in its own address space. When the application makes a request for such objects, VLF checks its dataspace to see if it is there. If affirmative, VLF can rapidly retrieve it without needing a DASD I/O. These data objects may contain copy of programs.

Data objects should be small-to-moderate in size, named according to the VLF naming convention, and associated with an installation-defined class of data objects.

Not all types of data objects can be stored in the VLF dataspaces. Only certain IBM products or components are VLF exploiters, such as:

- LLA (for load modules)
- TSO/E (for REXX and CLIST procedures)
- Catalog address space (CAS) for user catalog entries
- RACF records from its database

Since VLF uses virtual storage for its dataspaces, there are performance considerations that each installation must weigh when planning for the resources required by VLF.
Using VLF with LLA
You obtain the most benefit from LLA when you have both LLA and VLF. You should plan to
use both. When used with VLF, LLA reduces the I/O required to fetch load modules from the
DASD by causing selected load modules to be staged in VLF dataspaces.

LLA does not use VLF to manage library directories. When using LLA without VLF, LLA
eliminates only the I/O that the system would use in searching for library directories on DASD.

VLF considerations
Before you can take full advantage of implementing VLF to improve your system
performance, there are several factors you have to consider. Some of these factors are:

- VLF works best with two kinds of data:
  - Data objects that are members of partitioned data sets, located through a partitioned
data set (PDS) concatenation.
  - Data objects that, while not PDS members, could be easily described as a collection of
    named objects that are repeatedly retrieved by many users.

If neither description fits your data objects, it is likely that you would not obtain any
performance benefit from VLF. Remember, there are storage overhead costs associated
with using VLF.

- VLF works best with relatively small objects because less virtual storage is expended to
  reduce the number of I/O operations.

- Like data in private storage, data stored through VLF is subject to page stealing. That is,
  VLF works best when a significant portion of the data is likely to remain in central storage
  and not be paged out to auxiliary storage. VLF is designed to improve performance by
  increasing the use of virtual storage to reduce the number of I/O operations. For a system
  that is already experiencing a central storage constraint, this strategy is probably not a
good choice. However, we should state that in the majority of installations, currently there
is plenty of available central storage.

VLF planning
Before you can use VLF, you have to:

1. Start VLF using the IBM-supplied default COFVLFxx parmlib member and a JCL
   procedure.

2. Update COFVLFxx to include the VLF classes associated with the applications or
   products.

Note: VLF is intended for use with major applications. Because VLF runs as a started task
that the operator can stop or cancel, it cannot take the place of any existing means of
accessing data on DASD. Any application that uses VLF must also be able to run without it.
COFVLFx parmlib member

You use the COFVLFx member of the SYS1.PARMLIB to define classes of VLF objects. To activate a class of VLF objects, VLF requires that a CLASS statement describing that group of objects be present in the active COFVLFx parmlib member (the member named on the START command used for VLF).

A VLF class is a group of related objects made available to users of an application or component. To get the most benefit from using VLF, consider its use for objects that are:

- Used frequently
- Changed infrequently
- Used by multiple end users concurrently

Some of the more important statements and parameters for COFVLFx are:

CLASS  Each group of objects that VLF processes must have a CLASS statement defining it. The CLASS statement indicates that the following parameters define that particular group of objects to VLF.

NAME(classname)  NAME(classname) specifies the name of the VLF class. For example, library looksaside (LLA) uses the class of VLF objects named CSVLLA. If the CLASS statement for CSVLLA is not included in the active COFVLFx parmlib member, LLA cannot use VLF, and many of the performance and operational benefits of LLA...
Chapter 4. LPA, LNKLST, and authorized libraries

will not be available. The classname can be 1 to 7 alphanumeric characters including @, #, and $.

**EDSN(dsn)]VOL(vol)]**

For a PDS class such as LLA, EDSN(dsn) identifies a partitioned data set name whose members are eligible to be the source for VLF objects in the class. The dsn can be 1 to 44 alphanumeric characters, including @, #, and periods (.). You do not need to specify the volume if the cataloged data set is the desired one. If the data set is not cataloged, or if you have multiple data sets with the same name on different volumes, you must specify VOL(vol). Multiple occurrences of the same data set name with a different volume are acceptable. However, if duplicate entries of the same data set name and the same volume occur, the system issues an informational message and ignores the redundant information. For the LLA class of objects it is recommended that the same PDSs defined in CSVLLAxx also be defined for VLF.

**EMAJ(majname)**

EMAJ identifies an eligible major name (majname) for a non-PDS class. For an IBM-supplied class, use the product information to determine if anything other than the names specified in the IBM-supplied default COFVLFx member are eligible. The majname can be 1 to 64 alphanumeric characters except comma(,), blank, or right parenthesis ()), for example EMAJ(LLA).

**MAXVIRT(nnn)**

The maximum amount of virtual storage that your installation wants VLF to use for the objects in the class. Unless you supply this value on the optional MAXVIRT parameter of the CLASS statement, VLF will use a default value. When you specify the MAXVIRT value, ensure that it is large enough to hold most or all of the frequently-used objects in a VLF class. An excessively small value tends to cause thrashing of the data in that VLF class, while an excessively large MAXVIRT value tends to increase the consumption of auxiliary storage because infrequently-used data is paged out, rather than discarded.

For more information, see *z/OS MVS Initialization and Tuning Reference*, SA22-7592. The following figure shows an example of a COFVLFx parmib member.
Starting and stopping VLF

To start VLF, you use the **START VLF,SUB=MSTR,N=xx** command. This command identifies the COFVLFxx parmlib member to build VLF. This command is issued by the IBM-supplied COMMND00 parmlib member during system initialization; the command can also be entered by the operator.

The parameters for the **S VLF** command are: **S VLF,SUB=MSTR[,NN=xx]**. This invokes the VLF procedure that starts the virtual lookaside facility (VLF), where:

**NN=xx** Indicates that the system is to start VLF using the COFVLFxx member of the SYS1.PARMLIB (default COFVLF00).

**Syntax for S VLF command:** **S VLF,SUB=MSTR[,NN=xx]**

To stop VLF use the **P VLF** command.

The parameter for the **P VLF** command is:

**VLF** The jobname assigned to the virtual lookaside facility. Using this parameter stops VLF with the message COF033I.

**Note:** Stopping VLF can degrade your system performance.
4.21 Authorized program facility (APF)

Each CPU can run in supervisor or problem state as indicated by bit 15 in the current PSW. When in problem mode state (PSW bit 15 ON), the CPU refuses to execute a privileged instruction, generating a program interrupt with interrupt code X'0002'. This interrupt will cause the running task to abend with a completion code X'OC2'. All privileged instructions share the fact that if they are misused, it may jeopardize the integrity and the security of the multi-transaction z/OS system.

Also, certain SVC routines when misused by the caller program may compromise system integrity and system security. Access to these routines must be restricted to only authorized programs.

In order to protect the system, z/OS introduced the concept of Authorized Program Facility (APF). Only load modules from an APF task can invoke the APF protected SVCs. A task is APF protected when all of its load modules are APF authorized. If just one load module running in a task is non-APF authorized, the task looses its APF state forever. The reason for this is to prevent programs from counterfeiting a load module in the load module flow of an authorized job step task. Thus, if a load module from a non-authorized task tries to execute SVCs that require APF authorization, z/OS abnormally ends the task and issues a completion code X'306' and reason code X'04'. Logically, if the load module is running in supervisor state or PSW keys from 0 to 7, it can invoke any SVC routine. Recall that all the load modules in the MLPA must be APF authorized.

**Application programs usually:**

- Reside in non-authorized libraries
- Execute in problem state
- Use storage key 8

![Authorized libraries](image)
There are two conditions that a load module needs to fulfill in order to be APF authorized, as follows:

- Use a linkedit step with the loader utility program with authorization code (AC) equal to one. This state is presented in a bit setting in the PDS/PDSE directory entry for the load module.
- The module must be stored in an APF library.

**Authorized (APF) libraries overview**

Libraries that contain authorized programs are known as authorized libraries. Following is a list of APF libraries:

- SYS1.LINKLIB
- SYS1.SVCLIB
- SYS1.LPALIB
- An authorized library specified by your installation

**Note:** By default, the libraries in the LNKLST concatenation are considered authorized unless you specified LNKAUTH=APFTAB in the IEASYSxx parameter list. However, if the system accesses the libraries in the LNKLST concatenation through JOBLIB or STEPLIB DD statements, the system does not consider those libraries authorized unless you specified the library name in the APF list by using either the IEAAPFxx or the PROGxx parmlib member. If a JCL DD statement concatenates an authorized library in any order with an unauthorized library, the entire set of concatenated libraries is treated as unauthorized. SYS1.LPALIB is treated as an authorized library only while the system builds the pageable link pack area (PLPA) using the LPALSTxx parmlib member. All load modules in PLPA are marked as coming from an authorized library. When accessed through a STEPLIB, JOBLIB, or TASKLIB DD statement, SYS1.LPALIB is considered an authorized library only if you have included it in the APF list.

**Link-editing load modules with AC=1**

You can use the PARM field on the link-edit step to assign the APF authorization code to a load module. This method causes the Binder to consider every load module created by the step to be authorized. If no authorization code is assigned in the Binder step, the AC=0 default is considered. To assign an authorization code using JCL, code AC=1 in the operand field of the PARM parameter of the EXEC statement.

    //LKED   EXEC  PGM=HEWL,PARM='AC=1',...

**Guidelines for using APF**

When you use APF authorization, you must control which programs are stored in the authorized libraries. If the first load module in a program sequence is authorized, the system assumes that the flow of control to all subsequent load modules is known and secure as long as these subsequent load modules come from authorized libraries. To ensure that this assumption is valid you should:

- Ensure that all programs that run as authorized programs adhere to your installation's integrity guidelines.
- Ensure that no two load modules with the same name exist across the set of authorized libraries. Two load modules with the same name could lead to an accidental or deliberate mix-up in load module flow, possibly introducing an integrity exposure.
- Linkedit with the authorization code (AC=1) only the first load module in a program sequence. Do not use the authorization code for subsequent load modules; they must be naturally APF authorized. If they are not, an x'306' abend is produced.
4.22 Authorizing libraries

Specifying program libraries to be APF authorized
The APF list is built during an IPL using those libraries specified in the IEAAPFx (not recommended) or PROGxx parmlib members, as indicated by the APF and PROG parameters in IEASYSxx, or from the operator's console at system initialization.

Note: You can also dynamically modify the APF list after IPL, but only when you have used the dynamic APF format in the PROGxx.

IEAAPFx parmlib member coding
The use of IEAAPFx member in the SYS1.PARMLIB is not recommended and it is not covered in this book.

PROGxx parmlib member coding
You can use the APF statement in PROGxx member to specify:
- The format of the APF-authorized library list, whether it is dynamic or static.
- Program libraries to be added to the APF list.
- Program libraries to be deleted from the APF list.
The statements and parameters for the APF statement are:

**FORMAT(DYNAMIC|STATIC)**  Specifies that the format of the APF list is dynamic or static.

**ADD|DELETE**  Indicates whether you want to add or delete a library from the APF list.

**DSNAME(dsname)**  Name of the library that you want to add to or delete from the APF list.

**SMS|VOLUME(volume)**  The identifier for the volume containing the library specified on the DSNAME parameter, which is one of the following:

- **SMS**, which indicates that the library is SMS-managed or it has a storage class associated.
- A six character identifier for the volume.
- *****, which indicates that the library is located on the current SYSRES volume.
- *MCAT*, which indicates that the library is located on the volume containing the master catalog.

The following is an example of a PROGxx definition:

```
APF FORMAT(DYNAMIC)  
APF ADD  
   DSNAME(SYS1.VTAMLIB)  
   VOLUME(******)  
APF ADD  
   DSNAME(SYS1.SICELINK)  
   VOLUME(******)  
APF ADD  
   DSNAME(SYS1.LOCAL.VTAMLIB)  
   VOLUME(TOTCAT)  
APF ADD  
   DSNAME(ISP.SISPLOAD)  
   VOLUME(*MCAT*)  
```

**Note:** The system automatically adds SYS1.LINKLIB and SYS1.SVCLIB to the APF list at IPL. If you specify a dynamic APF list format in PROGxx, you can update the APF list at any time during normal processing or at IPL. You can also enter an unlimited number of libraries in the APF list.

If you specify a static APF list format in PROGxx, you can define the list only at IPL, and are limited to defining a maximum of 255 library names (SYS1.LINKLIB and SYS1.SVCLIB, which are automatically placed in the list at IPL, and up to 253 libraries specified by your installation).

**Syntax format for APF statement:**  
APF FORMAT(DYNAMIC|STATIC) APF ADD | DELETE  
DSNAME(dsname) SMS | VOLUME(volname)  

The following is an example of a PROGxx definition:
4.23 Dynamic APF functions

- APF statement in PROGxx parmlib member
- SETPROG APF operator command
- D PROG,APF operator command

Managing dynamic APF

You can use the following ways to update the content of the APF table dynamically:

- Use PROGxx parmlib member which includes the appropriate APF statement to define the change.
- The SETPROG APF operator can also initiate a change to the APF table.
- The DISPLAY APF command can be used to display the list of libraries authorized by APF.

Using the PROGxx parmlib member

As mentioned in the previous section, you can use the APF statement to add or delete libraries from the APF list. To delete a library from the APF list use the following command:

Example of the APF DELETE: APF DELETE DSNAME(SCRIPT.R40.DCFLOAD) VOLUME(MPRES2)

Activate the change by using a SET PROG=xx command as follows:

SET PROG=T4
IIE252I MEMBER PROGT4 FOUND IN SYS1.PARMLIB
CSV410I DATA SET SCRIPT.R40.DCFLOAD ON VOLUME MPRES2 DELETED FROM APF LIST
IIE536I PROG VALUE T4 NOW IN EFFECT
To add a library to the APF list use the following command:

```
Example of the APF ADD: APF ADD DSNAME(MYPROG.LOADLIB) VOLUME(MPRES3)
```

Activate the change by using a SET PROG=xx command as follows:

```
SET PROG=T5
IEE252I MEMBER PROGT5 FOUND IN SYS1.PARMLIB
CSV410I DATA SET MYPROG.LOADLIB ON VOLUME MPRES2 ADDED TO APF LIST
IEE536I PROG VALUE T5 NOW IN EFFECT
```

### Using the SETPROG APF command

Use the SETPROG APF operator command to perform the following functions:

- Change the format of the authorized program facility (APF) list from static to dynamic, or static to dynamic.
- Add a library to a dynamic APF list.
- Delete a library from a dynamic APF list.

**Syntax for SETPROG APF command:**

```
SETPROG APF{,FORMAT={DYNAMIC|STATIC}}
{,{ADD|DELETE},DSNAME|LIBRARY=libname,{SMS|VOLUME=volume}}
```

To change the format of the APF list to dynamic:

```
SETPROG APF,FORMAT=DYNAMIC
CSV410I APF FORMAT IS NOW DYNAMIC
```

To add a library to the APF list:

```
SETPROG APF,ADD,DSNAME=SCRIPT.R40.DCFLOAD,VOLUME=MPRES2
CSV410I DATA SET SCRIPT.R40.DCFLOAD ON VOLUME MPRES2 ADDED TO APF LIST
```

To delete a library from the APF list:

```
SETPROG APF,DELETE,DSNAME=SCRIPT.R40.DCFLOAD,VOLUME=MPRES2
CSV410I DATA SET SCRIPT.R40.DCFLOAD ON VOLUME MPRES2 DELETED FROM APF
```

**Note:** If you try to add to or delete from an APF list that is in a static format, the system responds with a CSV411I message, as follows:

```
SETPROG APF,DELETE,DSNAME=SCRIPT.R40.DCFLOAD,VOLUME=MPRES2
CSV411I ADD/DELETE IS NOT ALLOWED BECAUSE APF FORMAT IS STATIC
```

### Using the DISPLAY APF command

You can use the DISPLAY APF command to display one or more entries in the list of APF-authorized libraries. Each entry in the APF list display contains:

- An entry number
- The name of an authorized library
- An identifier for the volume on which the authorized library resides (or *SMS*, if the library is SMS-managed)

**Syntax for DISPLAY APF command:**

```
D PROG,APF[,ALL ] [,DSNAME=libname
|,ENTRY=xxx |,ENTRY=(xxx-yyy) ],L={a|cc|cca|name|name-a} ]
```
To display the whole APF list:

```
D PROG,APF
CSV450I 05.18.16 PROG,APF DISPLAY 971
FORMAT=DYNAMIC
ENTRY VOLUME DSNAME
  1 MPRES1 SYS1.LINKLIB
  2 MPRES1 SYS1.SVCLIB
  3 MPRES1 CPAC.LINKLIB
  ...
  36 MPRES2 NETVIEW.V2R4M0.USERLNK
  37 MPRES2 NPM.V2R3M0.SFNMLMD1
  38 MPRES2 EMS.V2R1M0.SEMSLMD0
```

This number is the decimal entry number for each of the libraries defined in the APF list. To display the specific library at entry number 1:

```
D PROG,APF,ENTRY=1
CSV450I 05.24.55 PROG,APF DISPLAY 979
FORMAT=DYNAMIC
ENTRY VOLUME DSNAME
  1 MPRES1 SYS1.LINKLIB
```

To display all the libraries in the range from 1 to 5:

```
D PROG,APF,ENTRY=(1-5)
CSV450I 05.26.27 PROG,APF DISPLAY 981
FORMAT=DYNAMIC
ENTRY VOLUME DSNAME
  1 MPRES1 SYS1.LINKLIB
  2 MPRES1 SYS1.SVCLIB
  3 MPRES1 CPAC.LINKLIB
  4 MPRES1 ISF.SISFLOAD
  5 MPRES1 ISF.SISFLPA
```

**Note:** It is recommended that you use the PROGxx parmlib member instead of the IEEAAPFxx parmlib member to define the APF list, regardless of whether you plan to take advantage of the dynamic update capability. If you specify both the PROG=xx and the APF=xx parameters, the system places into the APF list those libraries listed in the IEEAAPFxx, followed by those libraries in the PROGxx. If you are currently using the IEEAAPFxx parmlib member to define the APF list, you can convert the format of IEEAAPFxx to a PROGxx format using an IEEAAPFPR REXX exec provided by IBM. For more information, see *z/OS MVS Initialization and Tuning Reference*, SA22-7592.
System Modification
Program/Enhanced (SMP/E)

SMP/E is a tool designed to manage the installation of software products on your z/OS system and to track the modifications you make to those products. Usually, it is the system programmer's responsibility to ensure that all software products and their modifications are properly installed on the system. The system programmer also has to ensure that all products are installed at the proper level so all elements of the system can work together. At first, that might not sound too difficult, but as the complexity of the software configuration increases, so does the task of monitoring all the elements of the system. To better understand this, let's take a closer look at your z/OS system and see how SMP/E can help you maintain it.

This chapter covers the following topics:
- SMP/E overview
- Concept of SMP/E element
- Data sets used by SMP/E
- Consolidate software inventory (CSI)
- SMP/E commands you need to know
- SMP/E dialogs
- Java archive (JAR) file support
- GIMZIP and GIMUNZIP introduction
- GIMXSID service routine
- SMP/E release levels
- SMP/E hints
5.1 SMP/E overview

SMP/E is the basic tool for installing and maintaining software in z/OS systems and subsystems. It controls these changes at the element level by:

- Selecting the proper levels of elements to be installed from a large number of potential changes
- Calling system utility programs to install the changes
- Keeping records of the installed changes

SMP/E is an integral part of the installation, service, and maintenance processes for CBPDOs, ProductPacs, ServicePacs and selective follow-on service for CustomPacs. In addition, SMP/E can be used to install and service any software that is packaged in SMP/E system modification (SYSMOD) format.

It can be run either using batch jobs or using dialogs under Interactive System Productivity Facility/Program Development Facility (ISPF/PDF). SMP/E dialogs help you interactively query the SMP/E database as well as create and submit jobs to process SMP/E commands.

These are some of the types of software that can be installed by SMP/E:

- Products and service provided in CBPDOs and CustomPac offerings
- Products and service from IBM Software Distribution Centers not provided in CBPDOs or CustomPac offerings
Service provided in Expanded Service Options (ESOs)

Other products and service

**SMP/E SYSMODs**

SMP/E can install software from any of these source, provided it is packaged as a *system modification*, or SYSMOD. When it processes SYSMODs, it installs the elements in the appropriate libraries and updates its own records of the processing it has done. It installs program elements into two types of libraries:

- **Target libraries**
  
  Target libraries contain the executable code needed to run your system (for example, the libraries from which you run your production system or your test system).

- **Distribution libraries**
  
  Distribution libraries (DLIBs) contain the master copy of each element for a system. They are used as input to the SMP/E GENERATE command or the system generation process to build target libraries for a new system. They are also used by SMP/E for backup when elements in the target libraries have to be replaced or updated.
5.2 SYSMODs

Software, whether it is a product or service, consists of *elements* such as macros, modules, source, and other types of data (such as CLISTs or sample procedures). For software to be installed by SMP/E, it must include control information for the elements. This information describes the elements and any relationships that the software has with other products or services that may also be installed on the same z/OS system. The combination of elements and control information is called a system modification, or SYSMOD. You make changes in your system to improve the usability or reliability of a product, such as to add some new functions to your system, upgrade some of the elements of your system, or modify some elements for a variety of reasons. In all cases, you are making system modifications.

**SYSMOD package**

The SYSMOD is the actual package containing information SMP/E needs to install and track system modifications. SYSMODs are composed of two parts:

- Modification control statements (MCS), designated by ++ as the first two characters, that tell SMP/E:
  - What elements are being updated or replaced.
  - How the SYSMOD relates to product software and other SYSMODs.
  - Other specific installation information.

- Modification text, which is the object modules, macros, and other elements supplied by the SYSMOD.
Types of SYSMODs
There are four types of SYSMODs:

- **Function SYSMODs**
  These introduce a new product, a new version or release of a product, or updated functions for an existing product into the system. There are two types of function SYSMODs:
  - A **base function** either adds or replaces an entire functional area in the system. It is a collection of elements (such as source, macros, modules, and CLISTS) that provides a general user function and is packaged independently from other functions. A base function is packaged as a function SYSMOD on a RELFILE tape, identified by an FMID (function modification identifier). The FMID is a 7 character identifier that needs to be unique to distinguish one product from another. Function SYSMODs for base functions are applicable to any z/OS environment, although they may have interface requirements that require the presence of other base functions. Examples of base functions are SMP/E and z/OS.
  - A **dependent function** provides an addition to an existing functional area in the system. It is a collection of elements (such as source, macros, modules, and CLISTS) that provides an enhancement to a base function. It is called dependent because its installation depends on a base function already being installed. A dependent function is packaged as a function SYSMOD on a RELFILE tape, identified by an FMID. Function SYSMODs for dependent functions are only applicable to the parent base function. Each dependent function specifies an FMID operand on the ++VER MCS to indicate the base function to which it is applicable. Examples of dependent functions are the language features for SMP/E.

- **PTFs**
  These are IBM-supplied, tested fixes for reported problems. They are meant to be installed in all environments. PTFs may be used as preventive service to avert certain known problems that may have not yet appeared on your system, or they may be used as corrective service to fix problems you have already encountered. The installation of a PTF must always be preceded by that of a function SYSMOD, and often other PTFs as well. Each PTF has a unique, 7-character name called a SYSMOD ID.

- **APAR fixes**
  Authorized Program Analysis Reports (APARs) are temporary fixes designed to fix or bypass a problem for the first reporter of the problem. These fixes may not be applicable to your environment. The installation of an APAR must always be preceded by that of a function SYSMOD, and sometimes of a particular PTF. That is, an APAR is designed to be installed on a particular preventive-service level of an element. Each APAR has a unique, 7-character name called a SYSMOD ID.

- **User modifications** (USERMODs)
  These are SYSMODs built by you, either to change IBM code or to add independent functions to the system. The installation of a USERMOD must always be preceded by that of a function SYSMOD, sometimes certain PTFs, APAR fixes, or other USERMODs. Each USERMOD has a unique, 7-character name called a SYSMOD ID.

**Note:** If you want to package a user application program or new system function in SMP/E format, the correct way is to build a base or dependent function SYSMOD, not a USERMOD. See z/OS Packaging Rules, SC23-3695, for detailed information on packaging software.
5.3 Concept of SMP/E elements

An element, in SMP/E, is a part of a product, such as a macro, module, dialog panel, or sample code.

Following are the major element types dealt with in SMP/E. But, before we go further, we need to review some z/OS programming concepts, such as:

- **Machine instruction** - A machine instruction asks the CPU to execute a specified action. This action falls in one of seven classes: general, decimal, floating-point-support (FPS), binary-floating-point (BFP), control, I/O, and hexadecimal-floating-point (HFP) instructions. Any machine instruction has an operation code, which specifies the action to be performed, and operands, the data to be modified by the action.

- **Machine language** - Machine language is language that is used directly by the CPU.

- **Program** - Program is a general term for any combination of statements that can be interpreted by a computer or language translator, and that serve to perform a specific function. Programs fall in three general classes:
  - **Source code** - Source code is the logical combination of the source statements written in an specific language by a programmer that constitute the input to a language translator for a particular translation (Cobol, PL/I, Assembler). In Assembler, for example, it is possible for the programmer to use a structured language named Macros. Writing Macros makes Assembler programming easier. With a Macro, the
The programmer enters a few options and the Assembler transforms these options into object code.

- **Object code** - Object code is the output from a language translator (such as a compiler or an Assembler), where the source statements are converted to machine instructions. Before an object code can be executed, it must be processed by the linkage editor.

- **Executable code** - Executable code is the output of the **Binder**. Binder is a z/OS utility program that “link edits” object codes, thereby creating a fully executable code. The input for the Binder is the Object code (or even Executable code). Executable code is kept as special data set types, such as: PDS, PDSE, and HFS. **Program Management** is the name of the z/OS component that loads executable code in memory and manages its libraries. In z/OS there are two types of executable code:
  - Load modules stored in PDS data sets
  - Program Objects stored in PDSE or HFS data sets

**Note:** Program Objects remove many of the restrictions of the Load Modules and have support for new functionality.

**SMP/E element types**

Coming back to SMP/E, it works with SYSMODs as input. SYSMODs are modifications (usually corrections) to existing codes. Depending on the correction, the element type can be a macro or source code. In this case, it must be assembled and link edited by the Binder in order to generate the Load Module (or Program Object) replacing the former one. It also can be a specific Load Module (or Program Object) ready to replace the one in error.

Some of the SMP/E element types that are addressed by SYSMODs are the following:

- **SRC** - Module source that has been installed in the target or distribution libraries
- **MAC** - Macros that have been installed in the target or distribution libraries
- **MOD** - Modules used to create load modules in the target libraries
- **PROGRAM** - Program objects
- **HFS** - Elements installed in a hierarchical file system (HFS)
- **JAR** - Java Archive files
5.4 Changing the elements of the system

Introducing an element (Function SYSMOD)
To introduce new elements into the system with SMP/E, you can install a function SYSMOD. The function SYSMOD introduces a new product, a new version or release of a product, or updated functions for an existing product into the system. All other types of SYSMODs are dependent upon the function SYSMOD, because they are all modifications of the elements originally introduced by the function SYSMOD. Installing a function SYSMOD places all the product's elements in the system data sets, or libraries. Examples of these libraries are SYS1.LINKLIB, SYS1.LPALIB, and SYS1.SVCLIB. Figure 5-4 depicts the process of creating executable code in the production system libraries where the installation of a function SYSMOD link-edits object modules Mod1, Mod2, Mod3, and Mod4 to create load module LMOD2. The executable code created in load module LMOD2 is installed in the system libraries through the installation of the function SYSMOD.

```plaintext
++FUNCTION(FUN0001) /* SYSMOD type and identifier. */.
++VER(Z038) /* For MVS SREL */.
++MOD(MOD1) RELFILE(1) /* Introduce this module */.
     DISTLIB(AOSFB) /* in this distribution library. */.
++MOD(MOD2) RELFILE(1) /* Introduce this module */.
     DISTLIB(AOSFB) /* in this distribution library. */.
++MOD(MOD3) RELFILE(1) /* Introduce this module */.
     DISTLIB(AOSFB) /* in this distribution library. */.
++MOD(MOD4) RELFILE(1) /* Introduce this module */.
     DISTLIB(AOSFB) /* in this distribution library. */.
```
5.5 Fixing problems with an element (PTF SYSMOD)

PTF SYSMOD

When a problem with a software element is discovered, IBM supplies its customers with a tested fix for that problem. This fix comes in the form of a program temporary fix (PTF). Although you may not have experienced the problem the PTF is intended to prevent, it is wise to install the PTF on your system. The PTF SYSMOD is used to install the PTF, thereby preventing the occurrence of that problem on your system. Usually, PTFs are designed to replace or update one or more complete elements of a system function. In Figure 5-5, we see a previously installed load module LMOD2. If we want to replace the element Mod1, we should install a PTF SYSMOD that contains the module Mod1. This PTF SYSMOD replaces the element in error with the corrected element. As part of the installation of the PTF SYSMOD, SMP/E relinks LMOD2 to include the new and corrected version of Mod1. PTF SYSMODs are always dependent upon the installation of a function SYSMOD. In some cases, some PTF SYSMODs may also be dependent upon the installation of other PTF SYSMODs. These dependencies are called prerequisites (a typical PTF prerequisite is shown in Figure 5-9 on page 304). Following is an example of a simple PTF SYSMOD MCS.

```plaintext
++PTF(PTF0001)            /* SYSMOD type and identifier. */.
++VER(Z038) FMID(FUN0001)   /* Apply to this product. */.
++MOD(MOD1)                /* Replace this module */.
    DISTLIB(AOSFB)         /* in this distribution library. */.
...
... object code for module
...
5.6 Fixing a problem with an element (APAR SYSMOD)

You may sometimes find it is necessary to correct a serious problem that occurs on your system before a PTF is ready for distribution. In this situation, IBM supplies you with an Authorized Program Analysis Report (APAR). An APAR is a fix designed to quickly correct a specific area of an element or replace an element in error. You install an APAR SYSMOD to implement a fix, thereby updating the incorrect element. In Figure 5-6, the highlighted section is an area of Mod2 containing an error. The processing of the APAR SYSMOD provides a modification for object module Mod2. During the installation of the APAR SYSMOD, Mod2 is updated (and corrected) in load module LMOD2. The APAR SYSMOD always has the installation of a function SYSMOD as a prerequisite, and can also be dependent upon the installation of other PTF or APAR SYSMODs. Some APARs do not change modules; instead, they register problems while the final solution is being developed. Another APAR function is to give tips about customization and to alert for probable customer errors. Following is an example of a simple APAR SYSMOD.

```plaintext
++APAR(APAR001) /* SYSMOD type and identifier. */
++VER(Z038) FMID(FUN0001) /* Apply to this product */
    PRE(UZ00004) /* at this service level. */
++ZAP(MOD2) /* Update this module */
    DISTLIB(AOSFB) /* in this distribution library. */
...
... zap control statements ...
```
5.7 Customizing an element (USERMOD SYSMOD)

If you have a requirement for a product to perform differently from the way it was designed, you might want to customize that element of your system. IBM provides you with certain modules that allow you to tailor IBM code to meet your specific needs. After making the desired changes, you add these modules to your system by installing a USERMOD SYSMOD. This SYSMOD can be used to replace or update an element, or to introduce a totally new user-written element into the system. In either case, the USERMOD SYSMOD is built by you either to change IBM code or to add your own code to the system. In Figure 5-7, Mod3 has been updated through the installation of a USERMOD SYSMOD. Prerequisites for USERMOD SYSMODs are the installation of a function SYSMOD, and possibly the installation of other PTF, APAR, or USERMOD SYSMODs. Following is an example of a simple USERMOD SYSMOD.

```
++USERMOD(USRMOD1) /* SYSMOD type and identifier. */.
++VER(Z038) FMID(FUN0001) /* Apply to this product */.
++PRE(UZ00004) /* at this service level. */.
++SRCUPD(JESMOD3) /* Update this source module */.
DISTLIB(AOSFB) /* in this distribution library. */.
...
... update control statements ...  
...
```
SYSMOD prerequisites

As you have learned, PTF, APAR, and USERMOD SYSMODs all have the function SYSMOD as a prerequisite. In addition to their dependencies on the function SYSMOD:

- PTF SYSMODs may be dependent upon other PTF SYSMODs.
- APAR SYSMODs may be dependent upon PTF SYSMODs and other APAR SYSMODs.
- USERMOD SYSMODs may be dependent upon PTF SYSMODs, APAR SYSMODs, and other USERMOD SYSMODs.

Consider the complexity of these dependencies. When you multiply that complexity by hundreds of load modules in dozens of libraries, the need for a tool like SMP/E becomes apparent.
5.8 PTF replacement

PTF replacement
The importance of keeping track of system elements and their modifications becomes readily apparent when we examine the z/OS maintenance process. Often, a PTF contains multiple element replacements. In the example in Figure 5-8, PTF0001 contains replacements for two modules, MOD1 and MOD2. Although load module LMOD2 contains four modules, only two of those modules are being replaced.

But what happens if a second PTF replaces some of the code in a module that was replaced by PTF0001? Consider the example in Figure 5-9 on page 304.
5.9 PTF prerequisite

![Diagram showing PTF prerequisites](image)

**Figure 5-9  PTF prerequisites**

**PTF prerequisites**

In this example, PTF0002 contains replacements for MOD2 and MOD3. For MOD1, MOD2, and MOD3 to interface successfully, PTF0001 must be installed before PTF0002. That's because MOD3 supplied in PTF0002 may depend on the PTF0001 version of MOD1 to be present. It is this dependency that constitutes a prerequisite. SYSMOD prerequisites are identified in the modification control statements (MCS) part of the SYSMOD package.
5.10 Load module construction

In Figure 5-10, the same Mod2 module is present in LMOD1, LMOD2, and LMOD3. When a PTF is introduced that replaces the element Mod2, that module must be replaced in all the load modules in which it exists. Therefore, it is imperative that we keep track of all load modules and the modules they contain. You can now appreciate how complicated the tracking of system elements and their modification levels can become. Let's take a brief look at how we implement the tracking capabilities of SMP/E.

Tracking and controlling prerequisites
To track and control elements successfully, all elements and their modifications and updates must be clearly identified to SMP/E. SMP/E relies on modification identifiers to accomplish this. There are three modification identifiers associated with each element:

- **Function modification identifiers (FMIDs)** that identify the function SYSMOD that introduced the element into the system.
- **Replacement modification identifiers (RMIDs)** that identify the last SYSMOD (usually a PTF SYSMOD) to replace the element.
- **Update modification identifiers (UMIDs)** that identify the SYSMODs that have updated an element since it was last replaced.

SMP/E uses these modification identifiers to track all SYSMODs installed on your system. This ensures that they are installed in the proper sequence. Now that you realize the need for element tracking and know the types of things SMP/E tracks, let's look at how SMP/E performs its tracking function.
5.11 Data sets used by SMP/E

Some important SMP/E data sets:

- **SMPCSI**
- **SMPCNTL**
- **SMPHOLD**
- **SMLOG / SMLOGA**
- **SMPLTS**
- **SMPMTS**
- **SMPPTS**
- **SMPPTSNN**
- **SMPSCDS**
- **SMPSTS**
- **SMPPTFIN**
- **SMPRPT**
- **SMPOUT**
- **SMPSNAP**
- **SYSLIB**

**Figure 5-11 Data sets used by SMP/E**

**SMP/E data sets**

When SMP/E processes SYSMODs, it installs the elements in the appropriate libraries and updates its own records of the processing it has done. SMP/E installs program elements into two types of libraries:

- **Target libraries** contain the executable code needed to run your system (for example, the libraries from which you run your production system or your test system).
- **Distribution libraries** (DLIBs) contain the master copy of each element for a system. They are used as input to the SMP/E GENERATE command or the system generation process to build target libraries for a new system. They are also used by SMP/E for backup when elements in the target libraries have to be replaced or updated.

To install elements in these libraries, SMP/E uses a database made up of several types of data sets:

**SMPCSI (CSI)** These data sets are VSAM databases used by SMP/E to record status and other information about the various target and distribution libraries being supported. The data set specified by the ddname SMPCSI is the CSI containing the global zone. (This data set is also known as the master CSI.) These data sets can be reorganized by IDCAMS.

**SMPPTS** The SMPPTS data set (PTS) is used as a repository for SYSMODs. It contains one member for each SYSMOD that was received. Each member is called an MCS entry and is an exact copy of the SYSMOD as it was received from the SMPPTFIN data set. The name of an MCS entry...
matches the SYSMOD ID of the SYSMOD it contains. The PTS is related to the global zone that contain information about the received SYSMODs. Only one PTS can be used for a given global zone. Therefore, you can look at the global zone and PTS as a pair of data sets to be processed concurrently.

**SMPPTSnn**

SMPPTS spill data sets can be used to store SYSMODs when the SMPPTS data set becomes full. This type of processing is called spill processing. SMPPTS spill data sets are used by SMP/E in the same way as the primary SMPPTS data set is used. The first SMPPTS spill data set must be specified with a ddname of SMPPTS1, the second SMPPTS2, and so on, up to a maximum of SMPPTS99. Do not skip any ddnames in this sequence; if a spill data set is omitted, SMP/E ignores any data sets that may follow the omitted data set (for example, if you specify only SMPPTS1 and SMPPTS3, then SMP/E uses only SMPPTS1 and ignores SMPPTS3). You must specify a valid data set name for an SMPPTS data set.

**SMPPSTS**

This data set is available since SMP/E V3R1.

**SMPSCDS**

The SMPSCDS data set (SCDS) contains backup copies of target zone entries that are created during APPLY processing. The backup copies are used during RESTORE processing to return the entries to the way they were before APPLY processing. Each target zone must have its own SMPSCDS data set; that data set must be unique to that target zone. This SMPSCDS data set must also be used with the related distribution zone.

**SMPMITS**

This data set is a target library for macros that exist only in a distribution library (such as macros in SYS1.AMODGEN). This data set allows the current version of these macros to be used for assemblies during APPLY processing. Therefore, the MTS is related to a specific target zone, and each target zone must have its own MTS data set. The SMPMITS data set must be in the SYSLIB concatenation for APPLY and RESTORE processing. It can be in the SYSLIB concatenation for ACCEPT processing.

**SMPSTS**

The SMPSTS data set (STS) is a target library for source that exists only in a distribution library. This data set allows the current version of these modules to be used for assemblies during APPLY processing. Each target zone must have its own SMPSTS data set, which may not be shared by any other target zone. This SMPSTS data set can also be used with the related distribution zone.

**SMPLTS**

The SMPLTS data set is used by SMP/E to save the base version of a product's load modules that use callable services. To reduce SMPLTS space requirements, SMP/E now saves a base version of a load module in the SMPLTS data set only if it contains both CALLLIBS and XZMOD subentries. If a load module contains CALLLIBS subentries, but no XZMOD subentries, this load module is not saved in the SMPLTS.

**Note:** Since SMP/E Version 3 Release 2 or z/OS 1.5, the size of the SMPLTS is very much reduced when compared to prior SMP/E releases. In prior releases of SMP/E or z/OS it was a very large data set.

Other data sets used by SMP/E are known as the utility and work data sets. Some of the important utility and work data sets are:

**SMPTLIB**

This data set is used as temporary storage for relative files that are loaded from SMPPTFIN during RECEIVE processing. They are deleted when the
associated SYSMOD is deleted by REJECT, RESTORE, or ACCEPT processing.

**SMPCNTL**

Contains the SMP/E commands to be processed. *This data set may reside in a UNIX file system since SMP/E V3R1.*

**SMPNTS**

The SMPNTS (SMP/E Network Temporary Store) is a directory of UNIX file system files that is used for temporary storage of network transported packages that were received during SMP/E RECEIVE processing. *This data set is available since SMP/E V3R1.*

**SMPHOLD**

Contains ++HOLD and ++RELEASE statements to be processed by the RECEIVE command. This may refer to an actual data set, or it may refer to a file on a tape (such as file 4 on an ESO or Internet data set). *This data set may reside in a UNIX file system since SMP/E V3R1.*

**SMPLOG**

Contains time-stamped records of SMP/E processing. The records in this data set can be written automatically by SMP/E or added by the user through the LOG command. The data set also contains messages issued by SMP/E, as well as detailed information about the data set allocation. Each zone should have its own SMPLOG data set.

**SMPLOGA**

A secondary log data set (SMPLOGA) should be defined to hold log data when the SMPLOG data set is full. Otherwise, the extra log data is written to the SMPOUT data set, with the date and time stamp encrypted. Each zone should have its own SMPLOGA data set.

**SMPPTFIN**

Contains SYSMODs and ++ASSIGN statements to be processed by the RECEIVE command. It can refer to an actual data set or to a file on a tape (such as file 1 on a ESO tape). *This data set may reside in a UNIX file system since SMP/E V3R1.*

**SMPRPT**

Contains the reports produced during SMP/E processing. If SMPRPT is not defined, all report output goes to the SMPOUT data set. *This data set may reside in a UNIX file system since SMP/E V3R1.*

**SMPOUT**

Contains messages issued during SMP/E processing, as well as dumps of the VSAM RPL, if any dumps were taken. It may also contain LIST output and reports if the SMPLOG and SMPRPT data sets are not defined. *This data set may reside in a UNIX file system since SMP/E V3R1.*

**SMPSNAP**

The SMPSNAP data set is used for snap dump output. When a severe error occurs, such as an abend or severe VSAM return code, SMP/E requests a snap dump of its storage before doing any error recovery.

**SYSLIB**

The SYSLIB is a concatenation of macro libraries that are to be used by the assembler utility. For the APPLY and RESTORE processing, the data sets should be concatenated in this order:

- SMPMTS
- MACLIB
- MODGEN
- Target system macro libraries (such as libraries specified for SYSLIB on the ++MAC statement)
- Distribution macro libraries (such as libraries specified for DISTLIB on the ++MAC statement)

**Note:** Since SMP/E Version 3 Release 2 the data sets in the SYSLIB concatenation will be allocated only if an assembly operation will be performed during the APPLY, ACCEPT, and RESTORE commands. This reduces SMP/E processing to allocate the data sets, as well as eliminating possible contention for the data sets.
5.12 Dynamic allocation of SMP/E data sets

DD statements

//SMPMTS DD DSN=SMPE.MVST100.SMPMTS,DISP=SHR
//SMPCSI DD DSN=SMPE.GLOBAL.CSI,DISP=SHR
//SMPRPT DD SYSOUT=*  

DDDEF entries

Entry Type: DDDEF                               Zone Name: MVST100
Entry Name: SMPMTS                               Zone Type: TARGET

PROTECT:                          
DATAACLAS:               MGMTCLAS :
STORCLAS:                              DSNTYPE :

Dynamic allocation of SMP/E data sets

The processing of SMP/E commands requires a variety of data sets. You can either provide the DD statements for these data sets (such as in a cataloged procedure) or have SMP/E allocate the data sets dynamically. Dynamic allocation has the advantage that data sets are allocated only as they are needed; DD statements must successfully allocate all data sets, regardless of whether they are needed for the command being processed.

There are some drawbacks to using DD statements. For example, all the data sets defined by DD statements must be successfully allocated, regardless of whether they are needed for the command being processed. In addition, if you are running several SMP/E commands, you must be careful to use the correct DD statements for each command. If you are processing zones that are in different CSI data sets, you must make sure to provide a DD statement that points to each of those zones and their associated CSIs.

Sources of information for dynamic allocation

SMP/E can use several sources of information to allocate data sets dynamically:

- DDDEF entries
- SMPPARM member GIMDDALC
- Standard defaults

During any attempt to allocate a data set, SMP/E first looks for a DD statement specified in the job. If no DD statement was specified, SMP/E then looks for a DDDEF entry in the zone. If no DDDEF entry was found, SMP/E then checks to see if there is an SMPPARM data set. If
so, and there is a GIMDDALC member within it, SMP/E looks for a GIMDDALC control statement for the corresponding ddname.

**DDDEF Entries**

You can use DDDEF entries to provide SMP/E with information it needs to allocate any of the following:

- Permanent data sets, such as target libraries, distribution libraries, and SMP/E data sets
- Temporary data sets
- SYSOUT data sets
- Work data sets
- Pathnames for elements and load modules residing in a UNIX file system

The name of the DDDEF entry must match the ddname of the data set it describes and the entry must exist in the zone that uses the data set. DDDEF entries provide more flexibility than DD statements; they enable different zones to use different data sets for the same ddname and they use resources more efficiently because they allow SMP/E to allocate only the data sets it needs.

DDDEF entries can include the following information:

- Data set name
- Unit type
- Volume serial number
- Initial data set status: NEW, OLD, MOD, or SHR
- Final data set status: KEEP, DELETE, or CATALOG
- How the data set is to be allocated: blocks, cylinders, or tracks
- Primary and secondary values for space allocation
- Whether the data set should be RACF-protected
- Whether the data set is SMS-managed
- Directory information used to allocate the pathname for an element or load module residing in a UNIX file system.

**SMPPARM member GIMDDALC**

Another way to provide SMP/E with information about data sets is through GIMDDALC control statements in SMPPARM member GIMDDALC. It is used to specify data sets that are to be dynamically allocated by SMP/E. The following types of data sets may be specified in GIMDDALC:

- Data sets to be allocated to a SYSOUT class (or to the terminal for foreground execution)
- Data sets to be allocated as temporary data sets
- SMPTLIB data sets

**Note:** If you previously used module GIMMPDFT to define allocation information for temporary data set, you must now use member GIMDDALC in the SMPPARM data set; module GIMMPDFT no longer exists since SMP/E V3R1.

**Standard Defaults**

SMPOUT and SYSPRINT are critical for SMP/E to operate properly. Therefore, in case they are not defined, SMP/E has built-in defaults for them.

- SMPOUT is allocated either as SYSOUT (for background processing) or to the terminal (for foreground processing).
- SYSPRINT is allocated as SYSOUT.
5.13 How dynamic allocation works

Once SMP/E has determined which data sets are needed for the command it is processing, SMP/E checks whether DD statements have been provided for any of those data sets. SMP/E uses information from those DD statements in allocating the data sets to which they apply. If any data sets lack DD statements, SMP/E must allocate them dynamically. To get the information it needs to do this, SMP/E checks the following sources in the order shown:

- DDDEF entries. If the zone specified on the SET command contains a DDDEF entry for the required data set, SMP/E uses that entry to allocate the data set. Otherwise, it checks the next source.
- SMPPARM member GIMDDALC. If a GIMDDALC control statement has been defined in SMPPARM member GIMDDALC, SMP/E uses that information to allocate the data set. Otherwise, it checks the next source.
- Standard defaults. If the data set is for SMPOUT or SYSPRINT, SMP/E uses the standard default to allocate the data set. Otherwise, data set allocation fails.

**Note:** When a data set is part of a concatenation (such as the SYSLIB concatenation), SMP/E does not do the previously described checking. All data sets in a concatenation must be defined the same way. For example, if a DDDEF entry specifies a concatenation, all the specified entries must also be defined by DDDEF entries.
For the cross-zone phase of APPLY and RESTORE processing, a DD statement cannot be used to allocate the SYSLIB for a cross-zone load module. This library can be allocated only through a DDDEF entry in the cross zone containing the LMOD entry for the cross-zone load module.

The DD name SMPDUMMY is always allocated as a DUMMY data set. SMP/E ignores any allocation information specified for SMPDUMMY by a DDDEF entry or GIMDDALC member. If SMPDUMMY was previously allocated outside of SMP/E, SMP/E frees the SMPDUMMY DD and then reallocates it as a DUMMY data set.
5.14 Consolidated software inventory (CSI)

Consolidated software inventory
The CSI data sets contain all the information SMP/E needs to track the target and distribution libraries. The CSI contains an entry for each element in its system, which describes the following:

- Element name
- Element type
- History
- How the element was introduced into the system
- A pointer to the element in the target and distribution libraries

The CSI does not contain the element itself, but rather a description of the element it represents.

The organization of the CSI data set
In the CSI, entries for the elements in the distribution and target libraries are grouped according to their installation status. These groupings are known as SMP/E zones.
SMP/E zones
There are three types of zones in a CSI:

Global zone  Contains entries needed to identify and describe each target and
distribution zone to SMP/E and stores information about SMP/E
processing options. Contains status information for all SYSMODs
SMP/E has begun to process and holds exception data for SYSMODs
requiring special handling or that are in error. This data set is also
known as the master CSI.

Target zone  Contains information that describes the content, structure, and status
of the target libraries. It also contains a pointer to the related
distribution zone, which can be used in APPLY, RESTORE, and LINK
when SMP/E is processing a SYSMOD and needs to check the level
of the elements in the distribution libraries.

Distribution zone  Contains information that describes the content, structure, and status
of the distribution libraries. Each distribution zone also points to the
related target zone, which is used when SMP/E is accepting a
SYSMOD and needs to check if the SYSMOD has already been
applied in the target zone.
5.15 How to organize CSI data sets

How to organize CSI data sets
Before you allocate any CSI data sets, you must decide how to organize those data sets. There are two basic structures for CSI data sets:

- **Single CSI**
  
  In single CSI structure, you can define one CSI to keep track of all the system activity. The single CSI data has one global zone and one or more target and distribution zones. Among the advantages of using this structure are the following:

  - The single CSI data set optimizes the use of direct access storage.
  - The single CSI data set puts your whole establishment in one VSAM data set. This provides you with a single control point and one source of information for your whole system.

  **Note:** Single-CI systems do have a drawback. When SMP/E needs to process a zone, it cannot request access to that specific zone; it must request access to the CSI data set containing that zone. As a result, if you have a single-CI system, you can run only one background SMP/E job at a time.
Multiple CSI

Each zone resides in a separate VSAM data set. The target and distribution zones are connected by ZONEINDEX entries to a single global zone. The global zone must be in one of the CSI data sets.

How to allocate a CSI data set

After you have decided which CSI structure to adopt for your installation, you can allocate a CSI data set using the VSAM access method services.

CSI data sets are keyed VSAM clusters and are allocated by use of access method services. The GIMSAMPDU member in SYS1.SAMPLIB is a sample job to allocate and prime CSI and SMP/E operational data sets. The following sample job step, which is taken from the sample job in GIMSAMPDU, allocates a CSI data set with enough space to have multiple target or distribution zones and then initializes the CSI with the zpool record.

The following JCL is an example of allocating a CSI data set with enough space to have multiple target and distribution zones.

```
//DEFZONES EXEC PGM=IDCAMS
//SYSPRINT DD SYSOUT=* 
//GIMZPOOL DD DSN=SYS1.MACLIB(GIMZPOOL),DISP=SHR 
//SYSIN DD */
DEFINE CLUSTER(  
   NAME(SMPE.GLOBAL.CSI)  
   VOLUMES(volid) 
   CYLINDERS(100 10) 
   FREESPACE(10 5) 
   KEYS(24 0) 
   RECORDSIZE(24 143) 
   SHAREOPTIONS(2 3) 
   ) 
   DATA (  
   NAME(SMPE.GLOBAL.CSI.DATA) 
   CONTROLINTERVALSIZE(8192) 
   ) 
   INDEX (NAME(SMPE.GLOBAL.CSI.INDEX) 
   CONTROLINTERVALSIZE(4096) 
   ) 
   REPRO INFILE(GIMZPOOL) 
   OUTDATASET(SMPE.GLOBAL.CSI) 
/*
```

JCL example considerations

When coding the JCL, consider the following:

- The high-level qualifier should not be SYS1 if the CSI data set is to be cataloged in a user catalog. The low-level qualifier must be CSI.
- The CSI is a key-VSAM (KSDS) data set.
- SMP/E does not support cross-system sharing of the CSI; you cannot specify 4 as the cross-system value for SHAREOPTIONS.
5.16 Defining zones for your system

Once you have allocated and initialized the CSI data sets, you need to create within them the entries SMP/E uses to maintain your system. The first entries you need to define are the zone definition entries:

**GLOBALZONE entry**
A global zone is created by defining a GLOBALZONE entry. The GLOBALZONE entry contains processing related information for SMP/E. It is also used by SMP/E as an index to target and distribution zones, either in the same CSI or in different CSI data sets. The GLOBALZONE entry must be defined before you can do other processing for that global zone.

**TARGETZONE entry**
A target zone is created by defining a TARGETZONE entry. The TARGETZONE entry contains information SMP/E uses to process a specific target zone and the associated target libraries. It must be defined before you can do any other processing for that target zone.

**DLIBZONE entry**
A distribution zone is created by defining a DLIBZONE entry. The DLIBZONE entry contains the information SMP/E uses to process a specific distribution zone and the associated distribution libraries. It must be defined before you can do any other processing for that distribution zone.
After you have defined the zones for your system, you can create other entries. SMP/E zones contain two basic types of entries:

- Entries controlling SMP/E processing
  
  You generally define processing control entries through the SMP/E administration dialogs or with the UCLIN command.

- Entries describing the structure and status of the target and distribution libraries
  
  Status and structure entries are generally created by SMP/E when you install SYSMODs, run the JCLIN command, or copy entries from one zone to another.

**Note:** SMP/E provides a member in SYS1.SAMPLIB (GIMSAMPU) containing sample UCLIN statements to define entries for a basic z/OS system. You can access this member by use of standard system utilities. The sample definitions are syntactically correct and can be used as the basis for your CSI entries. This sample is not complete for all systems, but it is an example of the types of information various entries need. For examples of UCLIN to define entries, see the UCLIN command in *SMP/E Commands*, SA22-7771, which shows the UCLIN syntax for each entry type, and SMP/E Data Set Entries in *SMP/E Reference*, which contains a description of the syntax plus examples and notes on its use.
5.17 SMP/E commands you need to know

Now that you are familiar with SMP/E and what it can do, you are probably wondering what you need to know to get started using SMP/E. This section identifies some basic processing commands you need to know to use SMP/E. For more detailed information about these commands, see *SMP/E Commands*, SA22-7771.

**Setting the zone you want to work on**

Before processing SMP/E commands, you must first set the zone on which you want SMP/E to work (global, target, or distribution). You do this by issuing the `SET BOUNDARY` command. This command identifies the zone and, therefore, the libraries upon which subsequent SMP/E commands are to act. The `SET BOUNDARY` command can also be used to request a particular set of predefined processing options.

**Receiving the SYSMOD**

For SMP/E to install a SYSMOD (Function, PTF, APAR or USERMOD), the SYSMOD must be *received* into data sets that can be used by SMP/E. The RECEIVE command performs the task of copying the SYSMOD from the distribution medium to data sets used by SMP/E (SMPPTS, SMPTLIB, and global zone within the CSI). For the RECEIVE command, the `SET BOUNDARY` command must specify the global zone. The `RECEIVE` command allows you to assign the source ID specified on the `SOURCEID` operand of the command to SYSMODs found in the SMPPTFIN input stream, even if they are already received.
Rejecting SYSMODs
The REJECT command allows you to clean up the global zone, SMPPTS, and associated entries and data sets. REJECT is helpful if the SMPPTS is being used as a permanent database for all SYSMODs, including those that have been accepted. You can also use it to purge old data from the global zone and SMPPTS. However, sometimes you need to delete an already received SYSMOD. For the REJECT command, the SET BOUNDARY command must specify the global zone.

Note: The CHECK operand is now allowed on the REJECT command. The CHECK operand indicates whether REJECT should perform a trial run of the command without actually updating any zones or data sets. This provides a way to test for errors that might occur during actual processing and to receive reports on the changes that would be made.

Applying the SYSMOD
The APPLY command is used to cause SMP/E to install the elements supplied by a SYSMOD into the operating (or target) system libraries. For the APPLY command, the SET BOUNDARY command must specify the target zone associated with the target libraries in which the SYSMODs are installed.

Restoring the target libraries to the previous level
At times, you may want to remove a SYSMOD that has been applied to the target libraries. For example, perhaps you installed a fix for a problem and got unexpected results. If you have not yet accepted the SYSMOD into the distribution libraries, you can use the RESTORE command to remove it from the target libraries. For the RESTORE command, the SET BOUNDARY command must specify the target zone from which the SYSMODs should be removed. SMP/E uses the RELATED field in the TARGETZONE entry to determine which distribution zone describes the elements to replace the restored elements.

Accepting the SYSMOD
After you have performed a SYSMOD RECEIVE and APPLY, you need to accept the elements into the distribution libraries for backup. However, this should be done only after you are satisfied with the performance and stability of the elements of the SYSMOD. Once you accept a SYSMOD, you cannot restore its element to a previous level. The ACCEPT command updates the distribution libraries so they are available for backup of any future SYSMODs. Once you have accepted a SYSMOD into the distribution libraries, you cannot use RESTORE to remove it from the target libraries. For the ACCEPT command, the SET BOUNDARY command must specify the distribution zone associated with the distribution libraries where the SYSMODs will be installed.

Displaying SMP/E data
The SMP/E CSI and other primary data sets contain a great deal of information you may find useful when installing new elements or functions, preparing user modifications, or debugging problems. There are several ways SMP/E allows you to display that information, as well as information about modules, macros, and other elements:

- LIST commands
- REPORT commands
- QUERY dialogs

Note: The CSI QUERY dialog allows a wildcard (pattern) for the entry name specification. A selection list of all entry names that match the specified pattern will be displayed when using a wildcard.
5.18 The RECEIVE process

The RECEIVE process
During receive processing, SMP/E reads data from tape files, DASD data sets, or files in a UNIX file system into the global zone, the SMPPTS, and temporary data (SMPTLIBs) for later processing.

The RECEIVE command processes data from the following sources:
- The SMPPTFIN data set is a sequential data set with LRECL=80, BLKSIZE=multiple of 80, and RECFM=FB, which contains the modification control statements (MCSs) defining the SYSMODs, as well as any related ++ASSIGN, ++FEATURE, and ++PRODUCT statements.

If you want to receive from multiple product tapes, you cannot concatenate them on a single SMPPTFIN DD statement. Instead, you must process each tape in a separate step, using separate SMPPTFIN DD statements. Refer to the documentation supplied with the tape for exact information on how to code the SMPPTFIN DD statement. For example, with a product tape, the program directory contains this information.

This data set may reside in the UNIX file system. Specify PATHOPTS(ORDONLY) and either FILEDATA=BINARY or FILEDATA=TEXT on the DD statement for this data set, if it is to reside in the HFS. If you specify FILEDATA=BINARY, each line of input must be padded with blanks to the 80-byte record length because there is no end of record marker for FILEDATA=BINARY. If you specify FILEDATA=TEXT, use the newline character (X'15') to mark the end of each line.
The SMPHOLD data set is a sequential data set with LRECL=80, BLKSIZE=multiple of 80, and RECFM=FB, which contains exception SYSMOD data (++HOLD and ++RELEASE statements).

This data set may reside in the UNIX file system. Specify PATHOPTS(ORDONLY) and either FILEDATA=BINARY or FILEDATA=TEXT on the DD statement for this data set if it is to reside in the HFS. If you specify FILEDATA=BINARY, each line of input must be padded with blanks to the 80-byte record length because there is no end of record marker for FILEDATA=BINARY. If you specify FILEDATA=TEXT, use the newline character (X'15') to mark the end of each line.

A package on a TCP/IP connected FTP server.

The SMPNTS directory.

When receiving a SYSMOD, SMP/E creates two entries:

- An MCS entry is created on the SMPPTS. This entry is an exact copy of the SYSMOD as it appeared in the SMPPTFIN data set.
- A SYSMOD entry is created in the global zone. This entry contains information that describes the installation requirements and element content of the SYSMOD.

When receiving the HOLDDATA, SMP/E also creates (or modifies) two entries:

- A HOLDDATA entry is created (or modified) in the global zone. This entry is an exact copy of the ++HOLD statements as they appeared in the SMPHOLD data set. The name of the entry is the ID of the SYSMOD affected by this ++HOLD statement. The HOLDDATA entry for a single SYSMOD can contain multiple ++HOLD statements.

Note: When a ++RELEASE statement is processed, SMP/E removes the corresponding ++HOLD statement from the HOLDDATA entry. When all ++HOLD statements are removed, the HOLDDATA entry is automatically deleted.

- A SYSMOD entry is created (or modified) in the global zone. This entry contains information that describes the exception SYSMOD conditions.

- For each ++HOLD statement processed, SMP/E updates the global zone SYSMOD entry to add a HOLD reason ID subentry. There are three types of HOLD reason ID subentries, HOLDERROR, HOLDSYSTEM, and HOLDUSER, corresponding to the three categories of exception SYSMODs.

Note: When a ++RELEASE statement is processed, SMP/E removes the corresponding reason ID from the global zone SYSMOD entry.

Managing exception SYSMOD through HOLDDATA

In SMP/E, when we speak of exception data, we are usually referring to HOLDDATA. HOLDDATA is often supplied for a product to indicate a specific SYSMOD should be held from installation. Reasons for holding a SYSMOD can be:

- A PTF is in error, normally known as PE, and should not be installed until the error is corrected (ERROR HOLD).
- Certain system actions may be required before SYSMOD installation (SYSTEM HOLD).
- The user may want to perform some actions before installing the SYSMOD (USER HOLD).
5.19 Sources of HOLDDATA

The main sources of HOLDDATA provided by IBM are:

- **Custom Build Product Delivery Option (CBPDO) tapes**
  
  This contains HOLDDATA that has been customized to your product set. That is, it contains only data applicable to PTFs for those products within a given feature that you have ordered.

- **Expanded Service Option (ESO) tapes**
  
  IBM regularly creates the service levels shipped on these tapes, then custom-builds ESOs for users and makes the tapes available through either subscription orders or special request orders.

- **Preventive service planning (PSP)**
  
  Once a service level has been created, there is no further opportunity to change the HOLDDATA on that tape, even though new errors are reported. PSP files have been set up to hold this additional HOLDDATA.

- **IBM Web pages service**

**Note:** Figure 5-19 shows the complete process of a file transfer RECEIVE, not only HOLDDATA. The IBM Web pages service is shown in the left part of the figure, which also shows the back and forth dialogues between IBM and the customer commonly associated with these services.
5.20 Reports for RECEIVE processing

- **Summary Report**
  - Listing with all SYSMODs processed
- **Exception SYSMOD Data Report**
  - Quick summary of HOLDDATA information
- **File Allocation Report**
  - Listing of all data sets used
- **Receive Product Summary Report**
  - Summarize for ++FEATURE and ++PRODUCT MCS

![Figure 5-20 RECEIVE processing reports](image-url)

**RECEIVE processing reports**
When RECEIVE processing is complete, the reports described in this section will help you to analyze the results.

**Summary report**
A Summary report provides you with a listing with all the SYSMODs that were processed during the RECEIVE command run. It shows you which SYSMODs were received, which were not received, and why they were not received. An example of a RECEIVE Summary report follows.
Sample RECEIVE Summary report

<table>
<thead>
<tr>
<th>SYSMOD</th>
<th>STATUS</th>
<th>TYPE</th>
<th>SOURCEID</th>
<th>STATUS FIELD</th>
<th>COMMENTS</th>
</tr>
</thead>
<tbody>
<tr>
<td>UQ01266</td>
<td>NOT RECEIVED</td>
<td>PTF</td>
<td>PUT9710</td>
<td>NO APPLICABLE ++VER</td>
<td>1 NOT ASSIGNED</td>
</tr>
<tr>
<td>UQ09543</td>
<td>NOT RECEIVED</td>
<td>PTF</td>
<td>PUT9710</td>
<td>ALREADY RECEIVED</td>
<td>2 ALREADY RECEIVED</td>
</tr>
<tr>
<td>UQ09340</td>
<td>RECEIVED</td>
<td>PTF</td>
<td>PUT9710</td>
<td></td>
<td>3 RECEIVED</td>
</tr>
</tbody>
</table>

1 PTF UQ01266 was not received because there is no applicable subsystem or system release (SREL) defined in the GLOBALZONE that matches the ++VER statement.
2 PTF UQ09543 was not received because it has already been received before.
3 UQ09340 was successfully received.

Exception SYSMOD data report

This report provides you with a quick summary of the HOLDDATA information processed during the RECEIVE command run. It lists the SYSMODs requiring special handling or that are in error, and those SYSMODs no longer requiring special handling or that have had an error fixed. An example of an Exception SYSMOD data report follows.

Sample SYSMOD Data report

<table>
<thead>
<tr>
<th>SYSMOD</th>
<th>TYPE</th>
<th>STATUS</th>
<th>REASON</th>
<th>FMID</th>
<th>++HOLD MCS STATEMENTS</th>
</tr>
</thead>
<tbody>
<tr>
<td>UQ09660</td>
<td>SYS</td>
<td>HELD</td>
<td>ACTION</td>
<td>HDB4410</td>
<td>++ HOLD(UQ09660) SYS FMID(HDB4410)</td>
</tr>
</tbody>
</table>

1 UQ09660 is an exception SYSMOD. Normally, for exception SYSMOD with the reason ID as ACTION, you have to perform certain actions before you can install the SYSMOD. For example, you may have to IPL the system for the fix to take effect.

File allocation report

This report provides you with a list of data sets used for RECEIVE processing and supplies information about these data sets. An example of a File Allocation report follows.
receive product summary report

This report is produced at the completion of RECEIVE processing to summarize the processing that occurred for ++FEATURE and ++PRODUCT MCS. If no ++FEATURE and ++PRODUCT MCS are processed, this report is not generated. An example of a RECEIVE Product Summary Report follows.

| ++PRODUCT(5647-A01,2.5.0) DESCRIPTION(OS/390) SREL(Z038). | ++FEATURE(OS3250BA) DESCRIPTION(OS/390 Base) PRODUCT(5647-A01,2.5.0) FMID(HBB6605,HMP1B00). |
| ++FEATURE(OS3250DD) DESCRIPTION(OpenEdition DCE User Privacy DES) PRODUCT(5647-A01,2.5.0) FMID(JMB3125). |
| ++FEATURE(OS3250LD) DESCRIPTION(Language Environment Decryption) PRODUCT(5647-A01,2.5.0) FMID(JMWL755). |

receive command summary

When the RECEIVE command is used to load a SYSMOD into a SMP/E storage area, it does the following:

- Copies the MCS for each SYSMOD to the SMPPTS data set
- Loads elements into SMPTLIB data sets for SYSMODs using the relative file packaging method
- Records what is received in the global zone
  - SYSMOD entries
  - HOLDDATA entries
- Reports the results of processing
5.21 RECEIVE examples

- Receiving only HOLDDATA
- Receiving only SYSMOD
- Receiving both SYSMOD and HOLDDATA
- Receiving selected SYSMOD and HOLDDATA

How to receive only HOLDDATA

You must provide SMP/E with the most current HOLDDATA possible to get the most benefit from this support. It is usually available on IBM service Web pages, together with Recommended Service Upgrade (RSU). Recommended service upgrade (RSU) is a preventive service philosophy that applies to z/OS. RSU is intended to reduce the volume of PTFs customers must apply for preventive maintenance and to reduce the chance of encountering a PTF in error (PE), resulting in a more stable system. It is recommended that customers APPLY all RSU PTFs as preventive maintenance on their z/OS systems. However, customers must make the final decision as to what maintenance they will install.

For information about the latest recommended level of service, see the CST and RSU Web site:

There may be times when you do not want to receive the SYSMODs from a service tape, but you do want to receive the HOLDDATA. Because the HOLDDATA provides information about SYSMODs requiring special handling or that are in error, it is important for you to receive the HOLDDATA into the SMP/E storage repository as soon as possible.

Sample JCL to process only the HOLDDATA follows.
How to receive only SYSMODs

This example assumes that you have previously received the HOLDDATA from a service tape and are now ready to install the SYSMODs. Before you can install these SYSMODs (using the SMP/E APPLY and ACCEPT commands), you must first receive them. Sample JCL to process only the SYSMODs follows.

Sample JCL to process only SYSMODS

```
//RECSYSM JOB (),'MVSSP',NOTIFY=&SYSUID,CLASS=A,MSGLEVEL=(1,1),
// MSGCLASS=X
//SMPE  EXEC PGM=GIMSMP
//SMPPTFIN DD DISP=SHR,DSN=SYS1.OS251140.PTF,  
//            VOL=SER=S1140C,
//            LABEL=(2,SL),UNIT=3480
//SMPCNTL DD *
//          SET BDY (GLOBAL). 3
//          RECEIVE SYSMODS SOURCEID(MVSPUT1). 4
```

1 - SMPPTFIN DD statement indicates the data sets which contains MCSs defining the SYSMODs to be received.
2 - SYSMODs parameter indicates that only the data from SMPPTFIN should be received.
   SOURCEID specifies a one-to-seven character source identifier to be assigned to the SYSMODs being received. SMP/E assigns this source ID to all the SYSMODs processed by this RECEIVE command.

How to receive both SYSMOD and HOLDDATA

In the course of maintaining your system, you need to install both the SYSMODs and process the related HOLDDATA. Sample JCL to process both SYSMODs and HOLDDATA follows.
How to receive selected SYSMODs and HOLDDATA

The SMP/E RECEIVE command also allows you to select individual SYSMODs or exception HOLDDATA applicable to the selected SYSMODs. The following sample JCL causes SMP/E to receive two SYSMODs specified plus any HOLDDATA entries that are applicable to the SYSMODs.

Sample JCL to receive selected SYSMODS and HOLDDATA

```plaintext
//RECPFT2 JOB (),'MVSSP',NOTIFY=&SYSUID,CLASS=A,MSGLEVEL=(1,1),
   MSGCLASS=X
//SMP     EXEC PGM=GIMSMP
//SMPPTFIN DD DISP=SHR,DSN=SYS1.OS251140.PTF,
   VOL=SER=S1140C,
   LABEL=(2,SL),UNIT=3480
//SMPHOLD DD DISP=SHR,DSN=SYS1.OS251140.HOLDATA,
   VOL=SER=MPWRK1
//SMPCNTL DD *
   SET BDY (GLOBAL).
   RECEIVE S(UW41970,UW41979) 1
   SYSMODS
   HOLDDATA
   SOURCEID(MVSPUT1) ./*
```

1 - Only two SYSMODs and applicable HOLDDATA were received using this command.
5.22 The REJECT process

Rejecting SYSMODs

The SMP/E REJECT command allows you to clean up the global zone, SMPPTS, and associated entries and data sets. You can use the CHECK operand on the RECEIVE command to test for errors that might occur during actual processing of it. The REJECT processing deletes a SYSMOD’s global zone entry, HOLDDATA entry (if any), PTF MCS entry, and also scratches any TLIB data sets allocated for the SYSMOD. REJECT is helpful if the SMPPTS is being used as a permanent database for all SYSMODs, including those that have been installed. You can also use it to purge old data from the global zone and SMPPTS. There are times when you need to reverse the process of receiving SYSMODs into your system. After receiving a SYSMOD, you can use the SMP/E REJECT command to remove that SYSMOD from the PTS and the global zone.

Processing modes of the REJECT command

To use the REJECT command, you must first determine which processing mode of the command you want to use. The mode you choose depends on the data you want to delete.

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHECK</td>
<td>Use the CHECK operand on the RECEIVE command to test for errors that might occur during actual processing of it.</td>
</tr>
</tbody>
</table>

Note: The processing modes are mutually exclusive. No two modes can be used together.

There are five modes of REJECT processing:

- CHECK mode

Figure 5-22  Rejecting SYSMODs
▶ MASS mode
SMP/E rejects all SYSMODs that have been received but not installed.

▶ SELECT mode
SMP/E rejects specific SYSMODs that have been received but not applied.

▶ PURGE mode
SMP/E rejects all SYSMODs that have been accepted into the specified distribution zones. This is used when SYSMODs are not automatically deleted once they have been accepted into the distribution libraries. This is true when NOPURGE is coded in the OPTIONS entry used to process the distribution zone.

▶ NOFMID mode
SMP/E rejects all SYSMODs applicable to functions that are not part of the system. This can be used to delete service for all functions that have been deleted from the global zone. It can also be used to delete FEATURE and PRODUCT entries for all functions that have been deleted from the global zone.

Entries deleted by the REJECT command
Regardless of whichever REJECT processing mode you select, SMP/E will delete the following:

▶ The SMPPTS MCS entry
▶ The global zone SYSMOD entry
▶ The associated FMID subentry in the GLOBALZONE entry, as appropriate
▶ The eligible HOLDDATA entries
▶ The associated SMPTLIB data sets, if the SYSMOD was packaged in RELFILE format

Reports for REJECT processing
At the end of REJECT processing, output from the REJECT command includes reports, as well as statistics written to SMPOUT and SMPLOG.

Two reports are produced during REJECT processing:

▶ File Allocation report
  This report provides a list of data sets allocated during the REJECT process and also information regarding these data sets.

▶ REJECT Summary report
  This report is produced at the completion of REJECT processing to summarize the processing that occurred for SYSMODs and other data.

SMP/E writes statistics to SMPOUT and SMPLOG to summarize what happened during REJECT processing. These statistics follow the message issued at the completion of REJECT processing.

For more information regarding these reports, see *SMP/E Commands*, SA22-7771.
5.23 REJECT examples

- Rejecting in MASS mode
- Rejecting in SELECT mode
- Rejecting in PURGE mode
- Rejecting in NOFMID mode

**Figure 5-23 REJECT examples**

**REJECT examples**
The following examples are provided to help you to use the REJECT command.

**How to reject in MASS mode**
In MASS mode, you can reject all SYSMODs that have been received but not installed yet. You can use the following sample JCL to perform this task.

```
//REJSYSM JOB (), 'MVSSP', NOTIFY=&SYSUID, CLASS=A, MSGLEVEL=(1,1),
// MSGCLASS=X
//SMPE EXEC PGM=GIMSMP
//SMPCSI DD DSN=SMPE.GLOBAL.CSI,DISP=SHR
//SMPRPT DD SYSOUT=* 
//SMPOUT DD SYSOUT=* 
//SYSPRINT DD SYSOUT=* 
//SMPCNTL DD *
  SET BDY(GLOBAL) /* Set to global zone. */
  REJECT APARS /* Reject all received-only */
  FUNCTIONS /* SYSMODs. */
  PTFS
  USERMODS.
/*
```
Using the MASS mode, you can also reject only PTFs that have been received but not applied. The following commands show how it can be done.

```
SET      BDY(GLOBAL) .     /* Set to global zone.      */
REJECT . /* Reject all received-only PTFs. */
```

**Note:** This method may reject SYSMODs you wanted to keep, and if that happens you would have to receive them again.

You can also use the `REJECT` command to reject HOLDDATA from your system. Assuming that you want to delete a HOLDDATA entry with no associated SYSMOD entry, you can use the following commands to accomplish this task.

```
SET      BDY(GLOBAL) .     /* Set to global zone.      */
REJECT   S(MYMOD01)         /* For this SYSMOD,         */
          HOLDDATA .         /* reject the HOLDDATA.     */
```

**Note:** If no SYMMD types are specified on a `REJECT` command for MASS mode, SMP/E rejects only PTFs.

### How to reject in SELECT mode

Sometimes, you want to reject certain SYSMODs from your system. You can use the `REJECT` command in the SELECT mode if you have applied and accepted a USERMOD into your system. You want to reject the current version, update the SYSMOD, and then reapply and reaccept it. You can use the following commands to perform this task.

```
SET      BDY(GLOBAL) .     /* Set to global zone.      */
REJECT   S(UW04356)         /* For this SYSMOD,         */
          HOLDDATA .         /* reject the HOLDDATA.     */
```

**Note:** By default, the `REJECT` command will only reject SYSMODs that are received but not installed. However, you can specify the `BYPASS` operand to prevent SMP/E from checking where the SYSMODs have been installed.

You can also use the `REJECT` command to reject HOLDDATA from your system. Assuming that you want to delete a HOLDDATA entry with no associated SYSMOD entry, you can use the following commands to accomplish this task.

```
SET      BDY(GLOBAL) .     /* Set to global zone.      */
REJECT   S(W04356)         /* For this SYSMOD,         */
          HOLDDATA .         /* reject the HOLDDATA.     */
```

**Note:** The `REJECT` command will delete both the SYSMOD and its associated HOLDDATA entry if it exists in the system.

### How to reject in PURGE mode

When you have specified `NOPURGE` in the OPTIONS entry, SMP/E will not delete the GLOBAL SYSMOD and the SMPPTS MCS entry after you have accepted the SYSMODs. You can use the following commands to reject SYSMODs that have been accepted into your system.
How to reject in NOFMID mode

Assume you had received, applied, and accepted function HMX1101. The function was automatically deleted from the global zone and SMPPTS when it was accepted. You have also received service for the function. Assume you have now decided to install an updated version of the function. To prepare for this, you want to delete the FMID of the current function from the GLOBALZONE entry, as well as delete the service and associated HOLDDATA that were received for that function.

You can use the following commands to perform the delete.

```
SET BDY(GLOBAL) . /* Set to global zone. */
REJECT PURGE(DLIB1) . /* Reject SYSMODs installed in this DLIB zone */
SET BDY(GLOBAL) . /* Process global zone. */
REJECT DFMID(HMX1101) /* Delete FMID and reject */
        NOFMID . /* for FMIDs not in GZONE. */
```

Note: This deletes SYSMODs and associated HOLDDATA for all functions that are not defined in the GLOBALZONE entry. It is not limited to entries for HMX1101. To limit the REJECT command to specific functions, use the FORFMID operand in another REJECT mode.

Rather than manually determine which FMIDs to delete, you can use the sample programs GIMCRSAM and GIMPRSAM (provided in SYS1.SAMPLIB) to help you create a REJECT NOFMID command for the FMIDs that are superseded or deleted in the DLIB zones you specify.
5.24 The APPLY process

After the SYSMODs have been received, you can use the APPLY command to install them into the appropriate target system libraries. The APPLY command calls system utilities, which are responsible for the actual updating of those libraries.

Selecting SYSMODS

You can specify operands on the APPLY command that tell SMP/E which of the received SYSMODs are to be selected for installation in the target libraries. SMP/E checks to make sure all other required SYSMODs (prerequisites) have been installed or are being installed concurrently and in the proper sequence.

Selecting elements

During APPLY processing, SMP/E uses the information provided in the selected SYSMODs to determine which elements should be installed in the target libraries. The selection of elements is monitored by SMP/E to make sure that the correct functional level of each element is selected.

Checking the APPLY process

SMP/E provides you with an option to stop APPLY processing just before any updating takes place so you can ensure all prerequisites are satisfied before the installation of the SYSMODs. This helps you see what will happen (and helps you detect problem SYSMODs) without actually updating the target libraries.
Updating the target library

After the proper SYSMODs have been selected and the proper functional and service level of each element has been determined, and after ensuring that the installation of another SYSMOD does not cause any current service regress, the APPLY command directs SMP/E to call the system utilities. It is the system utilities that actually place the elements into the target libraries described in the target zone. The source of the elements is the SMPTLIB data sets, the SMPPTS data set, or the indirect libraries, depending on how the SYSMOD was packaged.

Note:
- Because the APPLY command updates the system libraries, you should never use it on a live production system. When you process the APPLY command, you should always use a copy of the target libraries and target zone. By using a copy, you minimize the risk of new code causing an outage of your system. This process of copying is called cloning.
- We recommend that you always use the CHECK subparameter before you update the libraries with the new version of the modules, even when applying in a test system. It can avoid unnecessary workload.

How SMP/E keeps track of APPLY processing

SMP/E updates the information about the SYSMODs that have been applied. Remember, the target zone reflects the contents of the target libraries. Therefore, after the utility work is complete, and the target libraries have been updated, the APPLY command records the functional and service levels of the new elements in the target zone.

- A SYSMOD entry is created in the target zone for each SYSMOD that has been applied. Element entries (such as MOD and LMOD) are also created in the target zone for those elements that have been installed in the target libraries.
- SYSMOD entries in the global zone are updated to reflect that the SYSMOD has been applied to the target zone.
- BACKUP entries are created in the SMPSCDS data set so the SYSMOD can later be restored, if necessary.

The APPLY process is controlled by:
- The information in the target zone reflecting the status and structure of the target system libraries
- Information on the SYSMODs indicating their applicability
- Information in the OPTIONS and UTILITY entries
- Operands on the APPLY command

Reports for Apply processing

When APPLY processing is complete, these reports will help you analyze the results:

- **SYSMOD Status Report** provides you with a summary of the processing that took place for each eligible SYSMOD, based on the operands you specified on the APPLY command. It shows you which SYSMODs were applied, which were not applied, and why.
- The **Element Summary Report** provides you with a detailed look at each element affected by APPLY processing. It tells you in which libraries the elements were installed.
- The **Causer SYSMOD Summary Report** provides you with a list of SYSMODs that caused other SYSMODs to fail, and describes the errors that must be fixed to successfully
process the SYSMODs. This report can reduce the amount of work involved in figuring out which errors caused SYSMODs to fail.

- The **File Allocation Report** provides you with a list of the data sets used for APPLY processing and supplies information about these data sets.

Additional reports may be produced depending on the work being done and the content of the SYSMODs. For more information about all the reports produced by the APPLY command (and samples of actual reports), see the APPLY command in *SMP/E Commands* SA22-7771.

**Summary**

As explained in this section, when the APPLY command is used to install a SYSMOD in the target libraries, the command does the following:

- Selects SYSMODs to install
- Checks that all other required SYSMODs have been (or are being) installed
- Based on SYSMODs, selects elements to install
- Directs SMP/E to call the system utilities to update the target libraries
- Records what is applied:
  - Target zone: Creates SYSMOD entries and element entries
  - Global zone: Updates SYSMOD entries
  - SMPSCDS data set: Creates BACKUP entries
- Reports the results of processing

Remember, you should never perform APPLY processing on a live production system!
5.25 APPLY examples

- Applying all SYSMODs
  - using SOURCEID for grouping SYSMODs
- Applying with GROUP
  - SMP/E automatically installs all requisites
- Applying with CHECK
  - SMP/E does not install SYSMOD, for testing only

Applying all SYSMODs from a given source

If the SOURCEID operand was used during RECEIVE processing to group all those SYSMODs processed, you can choose to install only that set of SYSMODS. This can be done with the SOURCEID operand of the APPLY command. Suppose you received an ESO containing service levels PUT9901 and PUT9902. The ESO contained ++ASSIGN statements that assigned each PTF a SOURCEID value corresponding to the service level that it is part of. Now you want to install all the applicable PTFs from those tapes into the target libraries described by zone MVSTST1. You can use the following sample JCL to perform this task.

```
//APPLY JOB 'accounting info', MSGLEVEL=(1,1)
//APPLY EXEC SMPPROC
//SMPLIB DD UNIT=3380, VOL=SER=TLIB01
//SMPCNTL DD *
  SET BDY(MVSTST1)        /* Process MVSTST1 tgt zone. */.
  APPLY SOURCEID(PUT9901, /* Process these service */
               PUT9902)    /* levels */.
               GROUP       /* and any requisites. */.
/*
```

Applying with the GROUP operand

At times, you may know that a particular SYSMOD is required on your system, but you may not know all its requisite SYSMODs. By using the GROUP operand of the APPLY command,
you can have SMP/E determine all the requisites and automatically install them. This method is often used during the installation of new functions. Suppose you want to install a new function HYY2102, plus all its service, plus any requisite SYSMODs. You can do this with the following commands.

| SET      | BDY(MVSTST1)       /* Process MVSTST1 tgt zone. */. |
| APPLY    | FORFMID(HYY2102)   /* For one function. */.       |
| FUNCTIONS PTFS | /* Function and PTFs */. |
| GROUP    | /* plus requisites. */. |

**Applying with the CHECK operand**

In this example, SMP/E was directed to automatically include SYSMODs needed for the selected function and service. At times, you may want to review which SYSMODs are included before you actually install them. This can be done by using the CHECK operand of the APPLY command in the following example.

| SET      | BDY(MVSTST1)       /* Process MVSTST1 tgt zone. */. |
| APPLY    | FORFMID(HYY2102)   /* For one FMID. */.       |
| FUNCTIONS PTFS | /* Functions and PTFs */. |
| GROUP    | /* plus requisites */. |
| CHECK    | /* in check mode. */. |

After running this command, check the SYSMOD Status Report to see which SYSMODs would have been installed if you had not specified CHECK. If the results are acceptable, run the commands again, without the CHECK operand, to actually install the SYSMODs.
5.26 The APPLY CHECK process

The purpose of this command is to determine:

- Whether any errors will occur while the new function is being applied (except for errors that occur as a direct result of an update, such as a target library running out of space). This includes missing DDDEF entries.
- Whether any requisite SYSMODs are missing.
- A list of target libraries that will be updated during the actual apply. This will allow you to back up those libraries before you apply the new elements.
- The SYSMODs, if any, that will be regressed.
- SYSMOD in hold exception status.
- Processing of online JCLIN.

Researcng the APPLY CHECK reports
As a result of running the APPLY CHECK job, SMP/E produces various messages and reports that you should now use to do further research. Here are some of the errors that may have been detected:

- Some DD statements may be missing. Check the program directory or the SMP/E Reference, SA22-7772, to determine why they are required and how they should be specified.
Some APAR fixes or USERMODs may be regressed. If so, you must determine why. For
APAR fixes, you have to get the version of the APAR fix applicable to the new product. For
USERMODs, you have to rework the modification to make it applicable to the new
function, or eliminate the modification if the product being installed provides the same
function. When doing the actual APPLY operation, you may need to specify the BYPASS
operand to inform SMP/E that you have resolved these problems.

Some prerequisite or requisite PTFs may be missing. If so, you should determine whether
they can be obtained. Some may already be on an ESO tape you have in-house but have
not received; others may not have been shipped, in which case you have to get an early
copy of them by contacting the IBM Support Center. Although you can also avoid these
conditions by using the BYPASS operand, you are advised not to do this because the
regressions have not been resolved.

Some elements may not have been selected for installation. For each such element, if the
current functional owner (that is, FMID) is an IBM product, there may not be a problem;
this condition is common and occurs because there are multiple functions with common
elements. Check the program directory or installation guide for the product you are
installing to determine whether this condition is normal or if it indicates a problem.

If the FMID is not one for an IBM product, further research is necessary. Contact the
current owner of the element to determine how that product is related to the one you are
installing.

Some of the PTFs may not have been selected for installation because of exception
SYSMOD conditions identified by the ++HOLD MCSs. When installing a new function, you
may want to research these PTFs further. You can use the reason ID and the comments
specified in the ++HOLD MCS to determine which of the following actions is most
appropriate:

– Bypass the condition using the BYPASS(HOLDERR) operand.
– Do not install the PTF.
– Obtain a fix for the APAR.

Getting additional SYSMODs
After doing the research step, you may decide that additional SYSMODs are needed. If so:

– Obtain the additional SYSMODs by using CBPDO, ESO, CSSF Information/Access,
  SoftwareXcel Extended, or the IBM Support Center.
– Receive the additional SYSMODs, using the same source ID value as used when
  processing the CBPDO tape.
– Rerun the APPLY CHECK job.
– Repeat this process until no errors are reported.
5.27 The RESTORE process

If you discover that a particular SYSMOD is causing a problem in your target libraries, you can remove it and replace the elements affected by it with the previous level of those elements, which is obtained from the backup (or distribution) libraries. The **RESTORE** command replaces the affected elements in the target libraries with the unchanged versions from the distribution libraries. You can use the **RESTORE** command to remove SYSMODs from the target libraries and restore them to a previous level. The RESTORE command reverses APPLY processing, but has no effect on ACCEPT processing.

Removing SYSMODs and selecting elements

SMP/E ensures the eligibility of the selected SYSMODs and checks whether other SYSMODs are affected before continuing with RESTORE processing. Because of the various relationships and dependencies among the many SYSMODs, this checking is very important to the integrity of your system. In fact, to ensure that the requisites for a SYSMOD being restored are processed appropriately, SMP/E may require the whole chain of prerequisites to be restored. During RESTORE processing, SMP/E uses the information provided in the selected SYSMODs to determine which elements in the target zone should be replaced by elements in the related distribution libraries. The selection of elements is monitored by SMP/E to make sure that the correct functional level of each element is selected.

When SMP/E is satisfied that the proper SYSMODs have been selected, it uses information from the target zone to determine which distribution zone describes the elements necessary to replace the SYSMOD’s elements in the target libraries. The RESTORE command directs...
SMP/E to call system utilities that replace the elements in the target libraries with the previous level of the elements from the related distribution libraries.

How SMP/E keeps track of RESTORE processing
SMP/E updates the information about the SYSMODs that have been restored. Remember, the target zone reflects the contents of the target libraries. Therefore, after the utility work is complete, and the target libraries have been updated, the target zone is updated to accurately reflect the status of those libraries. All information in the target zone pertaining to the restored SYSMOD is removed. The element entries in the target zone are restored to reflect the distribution zone level of the elements. The global zone SYSMOD entries and MCS statements, which are stored in the SMPPTS data set, are deleted for those SYSMODs that have been restored. Any SMPTLIB data sets created during RECEIVE processing are also deleted for the restored SYSMOD. SMP/E automatically performs this global zone clean-up, unless you specify otherwise.

Reports for RESTORE processing
Depending on the work being done and the content of the SYSMODs, additional reports may be produced. For more information about all the reports produced by the RESTORE command (and samples of actual reports), see SMP/E Commands, SA22-7771. When RESTORE processing is complete, these reports will help you analyze the results:

- The **SYSMOD Status Report** provides you with a summary of the processing that took place for each eligible SYSMOD, based on the operands you specified on the RESTORE command. It shows you which SYSMODs were restored, which were not restored, and why.
- The **Element Summary Report** provides you with a detailed look at each element replaced or modified by RESTORE processing. It tells you in which libraries the elements were restored.
- The **Causer SYSMOD Summary Report** provides you with a list of SYSMODs that caused other SYSMODs to fail, and describes the errors that must be fixed to successfully process the SYSMODs. This report can reduce the amount of work involved in figuring out which errors caused SYSMODs to fail.
- The **File Allocation Report** provides you with a list of the data sets used for RESTORE processing and supplies information about these data sets.

Summary
Not all SYSMODs can be restored. For example, SMP/E cannot restore a SYSMOD that deletes another SYSMOD or that deletes a load module during APPLY processing. When the **RESTORE** command is used to remove a SYSMOD from the target libraries it does the following:

- Removes the SYSMOD from the indicated target zone.
- Calls system utilities to replace the SYSMODs elements in the target libraries with elements from the related distribution libraries.
- Records what is restored:
  - Target zone: Restores element entries to reflect their distribution zone level and deletes all information about restored SYSMOD.
  - Global zone: Deletes SYSMOD entries and MCS statements in SMPPTS for restored SYSMOD. Any SMPTLIB data sets created during RECEIVE processing are also deleted for the restored SYSMOD. (This global zone processing is optional.)
  - SMPSCDSDS data set: Deletes BACKUP entries for restored SYSMOD.
- Reports the results of processing.
5.28 Restore examples

- Restoring a single SYSMOD
  - Removing 1 PTF

- Restoring multiple PTFs to remove 1 PTF
  - Using 2 methods

- Restoring PTFs with GROUP operand
  - Indicates that SMP/E to determine additional SYSMODs to be restored

---

**Figure 5-28  Restore examples**

**Restore command examples**
The following examples can help you to use the RESTORE command.

**Restoring a single SYSMOD**
Assume that you have applied only PTF UZ00001, that an error was detected during testing, and that you want to remove the PTF from your system. You can use the RESTORE command in the following example to do this.

```plaintext
SET BDY(TGT1)  /* Set to target zone. */.
RESTORE S(UZ00001) /* Restore 1 PTF. */.
```

If you want to clean up all of the SMP/E records for this PTF (the global zone and the SMPPTS data set), you can use the REJECT command after RESTORE processing completes, as shown in the following example.

```plaintext
SET BDY(GLOBAL)  /* Set to global zone. */.
REJECT S(UZ00001) /* Reject 1 PTF. */.
```

**Restoring multiple PTFs to remove one PTF**
Assume you have applied the PTFs named UZ00001, UZ00002, and UZ00003 to your system, and that during testing an error is found in module XYMOD01. Because the current
service level of that module is UZ00003 (we can say that the RMID of the module is UZ00003), you want to restore that PTF from the system.

You have two choices:

1. Restore PTF UZ00001, UZ00002, UZ00003, and then reapply UZ00001 and UZ00002, as shown in the following example.

   ```
   SET      BDY(TGT1)          /* Set to target zone.   */.
   RESTORE  S(UZ00001,         /* Restore all 3 PTFs.   */
              UZ00002,         /*                       */
              UZ00003)         /*                       */.
   APPLY    S(UZ00001          /* Then re-apply the two */
              UZ00002)         /* that may be ok.      */.
   SET BDY(TGT1)          /* Set to target zone.   */.
   RESTORE  S(UZ00003)         /* Restore the 1 bad PTF.*/.
   ```

2. Accept PTFs UZ00001 and UZ00002, if you are sure that they have no errors, then restore UZ00003 as shown in the following example.

   ```
   SET      BDY(DLIB1)         /* Set to DLIB zone.     */.
   ACCEPT   S(UZ00001,         /* Accept two good PTFs. */
              UZ00002)         /*                       */.
   SET BDY(TGT1)          /* Set to target zone.   */.
   RESTORE  S(UZ00003)         /* Restore the 1 bad PTF.*/.
   ```

The end result in both cases is that module XYMOD01 from PTF UZ00002 is in the target libraries.

**Restoring PTFs using the GROUP operand**

In the previous example, when you wanted to restore the three PTFs, you specified all three in the select list. In a simple case like this, that was very easy; in practice, however, many PTFs are related to one another, and it may not be easy to determine which PTFs must be restored in order to remove the bad one. The GROUP operand can be used to assist in determining this. The commands shown in the following example can be run to determine which PTFs must be restored to restore UZ00003.

   ```
   SET      BDY(TGT1)          /* Set to target zone.   */.
   RESTORE  S(UZ00003)         /* Restore this one PTF */
   GROUP    /* plus any related PTFs, */
   CHECK    /* in check mode this time. */.
   ```

After running these commands, the various SMP/E reports can be used to determine that PTFs UZ00001, UZ00002, and UZ00003 should be restored. You can then determine the correct action: restore all, or accept some and then restore.
5.29 The ACCEPT process

The ACCEPT process

You can use the ACCEPT process to install a SYSMOD in the distribution libraries. The ACCEPT process is very similar to the APPLY process with one important exception: ACCEPT processing is irreversible.

After you are satisfied that an applied SYSMOD has performed reliably in your target system, you can install it in your distribution libraries.

When you accept a PTF, be aware that if in the future you need to restore a PTF that changes the same module of the accepted PTF, this module will be copied from the DLIB to your target library and it will retrograde to the level of the last PTF accepted. If you have never accepted a PTF, the module will retrograde to the base level, or at least, to the level that was installed.

Selecting SYSMODs

You can specify operands on the ACCEPT command that tell SMP/E which of the received SYSMODs are to be selected for installation in the distribution libraries. SMP/E ensures that all other required SYSMODs have been installed or are being installed concurrently and in the proper sequence.

Selecting elements

During ACCEPT processing, SMP/E uses the information provided in the selected SYSMODs to determine which elements should be installed in the distribution libraries. The selection of
elements is monitored by SMP/E to make sure that the correct functional level of each element is selected.

**Updating the distribution libraries**

After the proper SYSMODs have been selected and the proper functional and service level of each element has been checked, SMP/E calls the system utilities (in the same manner as APPLY and RESTORE) to place the elements into the distribution libraries described in the distribution zone. The source of the elements is the SMPTLIB data sets, the SMPPTS data set, or the indirect libraries, depending on how the SYSMOD was packaged.

**Note:** When ACCEPT processing has been completed, there is no way it can be undone.

**How SMP/E keeps track of ACCEPT processing**

SMP/E updates the information about the SYSMODs that have been accepted. Remember, the distribution zone reflects the contents of the distribution libraries. Therefore, after the utility work is complete, and the distribution libraries have been updated, the distribution zone is updated to accurately reflect the status of those libraries.

- A SYSMOD entry is created in the *distribution zone* for each SYSMOD that has been accepted. Element entries (such as MOD and LMOD) are also created in the distribution zone for the elements that have been installed in the distribution libraries.

- *Global zone* SYSMOD entries and MCS statements in the SMPPTS data set are deleted for those SYSMODs that have been accepted into the distribution zone. Any SMPTLIB data sets created during RECEIVE processing are also deleted. If you do not want SMP/E to do this global zone clean-up, you have the option to indicate this to SMP/E, and the information is saved.

The ACCEPT process is controlled by:

- The information in the distribution zone reflecting the status and structure of the distribution libraries
- Information on the SYSMODs indicating their applicability
- Information in the OPTIONS and UTILITY entries
- Operands on the ACCEPT command

**ACCEPT CHECK process**

The purpose of the CHECK option is to perform a test run informing you of possible error conditions and providing reports of SYSMOD status, libraries that will be updated, regression conditions, and SYSMODs that will be deleted. During CHECK processing, the list of distribution zone entries is maintained in storage; data is written to the distribution zone as a temporary storage medium. CHECK processing deletes any data written to the distribution zone. Consequently, no permanent updates are made to the distribution zone.

We recommend that you always use the ACCEPT CHECK prior to accepting the SYSMODs.

**Reports for ACCEPT processing**

When ACCEPT processing is complete, these reports will help you analyze the results:

- The **SYSMOD Status Report** provides you with a summary of the processing that took place for each eligible SYSMOD, based on the operands you specified on the ACCEPT command. It shows you which SYSMODs were accepted, which were not accepted, and why.
- The **Element Summary Report** provides you with a detailed look at each element affected by ACCEPT processing. It tells you in which libraries the elements were installed.

- The **Causer SYSMOD Summary Report** provides you with a list of SYSMODs that caused other SYSMODs to fail, and describes the errors that must be fixed to successfully process the SYSMODs. This report can reduce the amount of work involved in figuring out which errors caused SYSMODs to fail.

- The **File Allocation Report** provides you with a list of the data sets used for ACCEPT processing and supplies information about these data sets.

Additional reports may be produced depending on the work being done and the content of the SYSMODs. For more information about all the reports produced by the ACCEPT command (and samples of actual reports), see *SMP/E Commands*, SA22-7771.

**Summary**

When the ACCEPT command is used to install a SYSMOD in the distribution (or backup) libraries, it does the following:

- Selects SYSMODs to install
- Checks that all other required SYSMODs have been (or are being) installed
- Based on SYSMODs, selects elements to install
- Directs SMP/E to call the system utilities to update the distribution libraries
- Records what is accepted:
  - Distribution zone: Creates SYSMOD entries and element entries.
  - Global zone: Deletes SYSMOD entries and MCS statements in SMPPTS. Any SMPTLIB data sets created during RECEIVE processing are also deleted. (This global zone processing is optional.)
- Reports the results of processing

Remember, once you have accepted a SYSMOD, it cannot be restored!
5.30 ACCEPT examples

- Accepting all SYSMODs
  - Using SOURCEID operand
- Accepting using GROUP operand
  - SMP/E includes all requisite SYSMODs not accepted
- Accepting using GROUPEXTEND operand
  - SMP/E includes superseding SYSMODs for requisite SYSMODs in error

ACCEPT examples
The following examples will help you use the ACCEPT command.

Accepting all SYSMODs from a given source
If you used the SOURCEID operand during RECEIVE processing to group all the SYSMODs processed, you may choose to install only that set of SYSMODs. You can do this with the SOURCEID operand of the ACCEPT command. Suppose you received an ESO containing service levels PUT9901 and PUT9902. The ESO contained ++ASSIGN statements that assigned each PTF a SOURCEID value corresponding to the service level it is part of. Now you want to install all the applicable PTFs from those tapes into the distribution libraries described by zone MVSDLB1. You can do this with the commands shown in the following example.

```
SET BDY(MVSDLB1) /* Process MVSDLB1 DLIB zone. */.
ACCEPT SOURCEID(PUT9901, PUT9902) /* Process these service levels */.
GROUP /* and any requisites. */.
```

Accepting with the GROUP operand
At times, you may know that a particular SYSMOD is required on your system, but you may not know all its requisite SYSMODs. You can use the GROUP operand of ACCEPT to have SMP/E determine all the requisites and install them automatically. This method is often used...
when a new function is being installed. Suppose you want to install a new function, HPT1234, with all its service and any requisite SYSMODs. You can do this with the commands shown in the following example.

| SET      | BDY(MVSDLB1) /* Process MVSDLB1 DLIB zone. */. |
| ACCEPT   | FORFMID(HYY1234) /* For one function. */. |
| FUNCTIONS| PTFS /* Functions and PTFs */. |
| GROUP    | /* plus requisites. */. |

The FORFMID operand indicates that only SYSMODs applicable to this function should be installed. The FUNCTIONS operand indicates that HYY1234 can be installed. The PTFS operand indicates that only PTFs for HYY1234 should be installed (no APARs or USERMODs are included). The GROUP operand indicates that all requisite SYSMODs should also be accepted. These requisites can be applicable to other functions, but may not be APARs or USERMODs.

**Accepting with the GROUPEXTEND operand**

Assume you want SMP/E to automatically include the requisites for some SYSMODs you plan to install. However, you are not sure whether all of the requisites are available. (They may not have been received, or they might be held because they are in error.) In these cases, you would like SMP/E to check whether a superseding SYSMOD is available for the unsatisfied requisites. To have SMP/E do this additional checking, you can use the GROUPEXTEND operand as shown in the following example.

| SET      | BDY(MVSDLB1) /* Process MVSDLB1 DLIB zone. */. |
| ACCEPT   | FORFMID(HYY1234) /* For one function. */. |
| FUNCTIONS| PTFS /* Functions and PTFs plus */. |
| GROUPEXTEND | /* requisites or superseded. */. |

SMP/E accepts HYY1234 and any functions or PTFs applicable to HYY1234. Because of the GROUPEXTEND operand, SMP/E also accepts all requisites for those SYSMODs, even if the requisites are not applicable to HYY1234. If SMP/E cannot find a requisite, it looks for a SYSMOD that supersedes the requisite and uses it to satisfy the requirement. Likewise, if a requisite is being held for an error reason ID, SMP/E looks for a SYSMOD that supersedes the requisite, or that either satisfies or supersedes its error reason ID, and uses it to satisfy the requirement.

**Note:** You must be careful in using the ACCEPT command. When you accept a SYSMOD, you cannot restore it by using SMP/E.
5.31 Other useful SMP/E commands

In the course of managing your system, 90 percent of the time you will only use the RECEIVE, APPLY, and ACCEPT commands. However, there are times when you need to use other SMP/E commands to perform a specific task, such as retrieving information from SMP/E data sets, or cloning a new target zone from the existing target zone.

Some of the more useful SMP/E commands are:

- **LIST command**
  You can use the LIST command to retrieve information stored in SMP/E data sets.

- **REPORT ERRSYSMOD command**
  This command helps you to identify exception SYSMODs and also any resolving SYSMODs for the held SYSMODs.

- **UCLIN command**
  With the UCLIN command, you can add, delete, or replace entries in the following SMP/E data sets:
  - SMPCSI
  - SMPMTS
  - SMPSCDS
  - SMPSTS

---

**Figure 5-31 Other useful SMP/E commands**
The UCLIN command only updates entries in SMP/E data sets, hence it does nothing to any elements or load modules in any product libraries.

**Note:** Be sure you understand the relationships between the various entries before you make any UCLIN changes, as this helps to ensure that any UCLIN changes made are complete and consistent with one another. Remember, SMP/E does not check how the UCLIN changes might affect the other entries.

- **UNLOAD command**
  Sometimes you want to make changes to a set of DDDEF entries in the target zone. Instead of using the SMP/E dialog and making changes to each DDDEF entry one by one, you can use the **UNLOAD** command, which causes SMP/E to unload all the DDDEF entries from the target zone. The output produced is in the form of UCLIN statements, to which you can make the necessary updates for the DDDEF entries.

- **ZONECOPY command**
  The **ZONECOPY** command can be used to copy an entire target or distribution zone from an existing CSI data set to another CSI data set. SMP/E copies the data from the input zone to the other CSI and renames the receiving zone. This is useful when you need to set up a new target or distribution zone based on the existing zones.

- **ZONEDELETE command**
  There are times when you want to delete the information about an old level of the product after installing a new level of product in its own target and distribution zone.

- **ZONERENAME command**
  Sometimes the current name of a zone does not conform to the naming standard established in your environment and thus you want to assign a new name to the zones. You can do that by using the **ZONERENAME** command, which allows you to change the name of an existing target or distribution zone.

In this section, we briefly introduce the usage of the **LIST** and **REPORT ERRSYSMODS** commands. For more information on the rest of the commands, see *SMP/E Commands*, SA22-7771.
5.32 Using the LIST command

- LIST command

- To display information for selected entries in:
  - Global zone, target zone, distribution zone
  - SMPPTS
  - SMPLOG
  - SMPSCDS

Figure 5-32 Using the LIST command

Using the LIST command

The SMP/E data sets (the global zone, target zones, distribution zones, SMPPTS, SMPLOG, and SMPSCDS) contain a great deal of information that you may find useful when installing a new function, preparing a user modification, or debugging a problem. You can use the LIST command to display that information.

To list entries in a CSI data set, you must specify the name of the zone containing the entries to be listed on the SET BOUNDARY command.

To list entries in a data set other than the CSI (such as the SMPLOG or SMPSCDS), you must specify the zone associated with that data set on the SET BOUNDARY command:

- SMPLOG
  Specify the zone containing the DDDEF entry for the particular SMPLOG data set to be listed.

- SMPSCDS
  Specify the target zone containing the DDDEF entry for the particular SMPSCDS data sets to be listed.

Note: Make sure that the data you request to be listed is valid for the specified zone type.
**Listing entries in a particular zone**

There are times when you need to check all the DDDEF entries defined in the target zone. You can use the sample JCL shown in the following example to perform this task.

```plaintext
//LIST   JOB {},'MVSSP',NOTIFY=&SYSUID,CLASS=A,MSGLEVEL=(1,1),
       //MSGCLASS=X
//SMPE   EXEC PGM=GIMSMP
//SMPCSI  DD DSN=SMPE.GLOBAL.CSI,DISP=SHR
//SMPRPT  DD SYSOUT=*  
//SMPOUT  DD SYSOUT=*  
//SYSPRINT DD SYSOUT=*  
//SMPCNTL DD *
   SET BDY (MVST100). /* Set to target zone */
   LIST DDDEF . /* List all DDDEF entries */
```

If you want to check all the DDDEF entries defined in the global zone and all the zones defined to that global zone, you can use the LIST command shown in the following example (the global and any zone defined to it can be used in the **SET BOUNDARY** command).

```plaintext
SET BDY (MVST100) .
LIST DDDEF ALLZONES .
```

Suppose you need to determine whether target zone MVST100 contains entries for any elements owned by function HXY1100. To do this, use the LIST command with the FORFMID operand, as shown in the following example.

```plaintext
SET BDY (MVST100) */ Set to target zone */
LIST SYSMOD PTFS /* List SYSMOD that are PTFS */
FORFMID (HXY1100) /* for this FMID. */
```

**Note:** If you just use the SYSMOD operand, SMP/E lists all SYSMOD entries in that zone specified in the **SET BOUNDARY** command. You can limit which SYSMOD entries are listed by coding one or more SYSMOD qualifiers, such as APARS, PTFS, FUNCTION, and so forth.

**Reports**

The following reports are produced during LIST processing:

- The File Allocation report
- The LIST Summary report

For more information about these reports, see *SMP/E Commands, SA22-7771*. 

---

354  ABCs of z/OS System Programming Volume 2
5.33 Using the REPORT ERRSYSMOD command

- **REPORT ERRSYSMOD**
  - To determine exception SYSMODs
  - To determine resolving SYSMODs for held SYSMODs
  - Writes SMP/E commands to SMPPUNCH for receiving, applying, and accepting resolving SYSMODs

**Using the REPORT ERRSYSMODS command**
This command helps you to determine whether any SYSMODs you have already installed are now exception SYSMODs. It also helps you to determine whether any resolving SYSMODs are available for held SYSMODs.

For target and distribution zones, REPORT ERRSYSMODS lists installed SYSMODs for which ++HOLD statements were subsequently received and whose error reason IDs have not yet been resolved.

For the global zone, REPORT ERRSYSMODS lists received SYSMODs for which ++HOLD statements with error reason IDs have been received.

**Note:** When using the REPORT ERRSYSMODS command, the SET BOUNDARY command must specify GLOBAL.

**Examples of the REPORT ERRSYSMODS command**
The following are some examples showing how you can use the REPORT ERRSYSMODS command to get the information that you want.

Assume you have received the latest HOLDDATA, and you want to know whether it affects any of the SYSMODs that have already been applied to both the target and distribution zone. To do this, use the REPORT ERRSYSMODS, as shown in the following example and notes.
There are situations where you are only interested in the effect of the HOLDDATA on a certain function SYSMOD, for example HBB6607. You can use the FORFMID operand to achieve the objective as is shown in the following example and note.

Example of use of the REPORT ERRSYSMODS command

```plaintext
SET BDY(GLOBAL).
REPORT ERRSYSMODS
   ZONES(TZONE1,DZONE1)
   BEGINDATE(07 01 02)
   ENDDATE(08 01 02).
```

1 - Remember you have to specify GLOBAL in the SET BOUNDARY (SET BDY) command when you use the REPORT ERRSYSMODS command.

2 - Specify the name of target and distribution zone to report on.

3 - The BEGINDATE and ENDDATE indicates the begin and end date of the ++HOLD statement received by SMP/E for the REPORT ERRSYSMODS processing. The format of the date is mm dd yy.

There are situations where you are only interested in the effect of the HOLDDATA on a certain function SYSMOD, for example HBB6607. You can use the FORFMID operand to achieve the objective as is shown in the following example and note.

Example of use of the FORFMID operand

```plaintext
SET BDY(GLOBAL)
REPORT ERRSYSMODS
   ZONES(TZONE1)
   FORFMID(HBB6607)
   BEGINDATE(07 01 02)
   ENDDATE(08 01 02).
```

1 - Specifying the FORFMID operand will limit the list of SYSMODs to those that have the ++HOLD statement with the FMID specified.

Reports for REPORT ERRSYSMODs

At the end of the REPORT ERRSYSMODS processing, information about the held SYSMODs and any resolving SYSMODs is written to the Exception SYSMOD report. At the same time, commands needed to install the resolving SYSMODs are provided in the SMPPUNCH data set.

- Exception SYSMOD report
  
  This report is produced at the completion of REPORT ERRSYSMODS processing during which exception SYSMOD checking was done and HELDERROR reason IDs were not resolved for SYSMODs installed in the specified zone.

  The report shows the exception SYSMODs that were previously installed, the HELDERROR reason IDs (APAR numbers) that have made them exception SYSMODs, resolving SYSMODs that have not yet been installed, and the hold class and hold symptoms for each APAR.

  The exception SYSMOD reports produced by a given REPORT ERRSYSMODS command are arranged alphanumerically by zone name. Each report begins on a new page. The information gathered for each zone is sorted in ascending order, first by FMID, then by SYSMOD name, then APAR number, and finally, by resolving SYSMOD.

  The following example and notes show an example of the exception SYSMOD report.
The SMPPUNCH data set

In order to help you to install resolving SYSMODs for exception SYSMODs, SMP/E writes the necessary commands to the SMPPUNCH data set:

- SET BOUNDARY
- RECEIVE (for unreceived resolving SYSMODs)
- RESETRC (sets the return codes for the preceding commands to zero)
- Either APPLY (for target zones) or ACCEPT (for distribution)

However, there are cases where nothing is written to SMPPUNCH for a specified zone. This occurs when:

- There are no exception SYSMODs for the specified zone.
- There are no resolving SYSMODs for any of the exception SYSMODs, or all resolving SYSMODs identified are held.
- The specified zone is the global zone.
- NOPUNCH operand was specified on the REPORT ERRSYSMODS command.

The following example shows an example of SMPPUNCH output.
SET BDY (GLOBAL). /* REMOVE COMMENT IF DOING RECEIVE
RECEIVE SELECT ( 
  UW50483
  UW50095
  UW49599
  .
  .
  UW55773
  UW56914 )
SYSMODS.
  REMOVE COMMENT IF DOING RECEIVE */
RESETC.
SET BDY (MPROTZ ).
APPLY SELECT ( /* UW50483 RESOLVES AW29065 FOR HBB6605 FMID(HBB6605) */
  UW52639 /* PTF RESOLVES AW29065 FOR HBB6605 FMID(HBB6605) */
  .
  .
  UW53498 /* PTF RESOLVES AW35984 FOR UW51679 FMID(HPRF220) */
  )
GROUP.

For more information on the LIST, REPORT ERRSYSMODS, and others SMP/E commands, see SMP/E Commands, SA22-7771.
5.34 SMP/E dialogs

--- SAMP/E PRIMARY OPTION MENU --- SAMP/E 33.07

1. SETTING - Configure settings for the SMP/E dialogs
2. ADMINISTRATION - Administer the SMPCSI contents
3. SYMMD MANAGEMENT - Receive SYMMD and HOLDDATA
4. QUERY - Display SMPCSI information
5. COMMAND GENERATION - Generate SMP/E commands
6. RECEIVE - Receive SYMMD, HOLDDATA and support information
7. MIGRATION ASSISTANT - Generate Planning and Migration Reports
8. DESCRIBE - An overview of the dialogs
9. TUTORIAL - Details on using the dialogs
10. WHAT IS NEW - What is New in SMP/E

Specify the name of the CSI that contains the global zone:
SMPCSI DATA SET ===>/ZOSR06.GLOBAL.CSI
(Leave blank for a list of SMPCSI data set names.)

Specify YES to have DD statements for SYMOUT and temporary
data sets generated. Specify NO, to use DDEFS.
Generate DD statements ===>/ NO

--- Figure 5-34 SMP/E dialogs ---

SMP/E dialogs

You can get to the SMP/E dialogs from the SMP/E primary option menu. To provide access to that menu, you must connect the dialogs to ISPF. Sample ISPF panels are provided with z/OS to enable panels for most z/OS elements, including SMP/E. These panels are in the SISPPENU data set after APPL Y processing. The panels supplied are:

- **SR@390** - This is an ISPF Primary Options Menu. It is identical to the ISR@PRIM Primary Options Menu, except that it includes the additional options 12 and 13, which point to the next two panels.
- **ISR@390S** - This is a secondary panel, with options used by system programmers and administrators, including SMP/E.
- **ISR@390U** - This is a secondary menu panel, including the options used by most ISPF users.

Use one of the methods documented in the Program Directory for this level of SMP/E to use ISR@390 instead of ISR@PRIM. The SMP/E dialogs will then be accessible through panel ISR@390S.
5.35 Customize the SMP/E dialogs

The access by ISPF to the SMP/E dialogs is faster and easier. Through these screens you can obtain functions such as generation of SMP/E jobs and submit of SMP/E processes. Also it is possible using dialogs to find any information about products, for example:

- Modules
- Macros
- Clist
- Which libraries these elements are stored in

Several examples are mentioned here; for complete details refer to the *SMP/E User’s Guide*, SA22-7773.

After you install the SMP/E dialogs, you can change the default values they use. When you select option 0 (SETTINGS) on the SMP/E Primary Option Menu, SMP/E displays panel GIM@PARM, which allows you to:

- Modify the values for allocating temporary SMP/E utility (SYSUTn) and SMP/E work (SMPWRKn) data sets. The options you specify are saved permanently in the ISPF profile pool for use later by other SMP/E dialog processes.
- Specify a data set name to be used by SMP/E for the SMPPARM data set during background execution. The SMPPARM data set is used to define exit routines and specify allocation information used by SMP/E processing. If a data set name is specified on panel
GIM@PARM, SMP/E generates an SMPPARM DD statement in all JCL jobs created by the SMP/E dialogs that invoke SMP/E.

**JOB statement customization**

If you have never entered a JOB statement on panels GIMCGSUB, GIMRCSUB, or GIMSB01, then SMP/E primes those panels with the default JOB statement shown in the following example.

```
//useridA JOB (ACCOUNT), 'NAME'
/*/ 
```

This initial default JOB statement is not customizable, but when you enter a JOB statement on panels GIMCGSUB, GIMRCSUB, or GIMSB01, the statement you enter is saved in your ISPF profile pool and will be used as the new default when you use those panels again.
5.36 Query selection menu

Let’s assume you want to find out which SYSMODs have been applied to a particular target zone on your system. You can accomplish this task using the QUERY SELECTION MENU and selecting the CSI QUERY, option 1, as shown in Figure 5-36.

To get to the Query dialogs, you select SMP/E (option 1) on the initial SMP/E dialog panel (CIDPGV2). Then, on the main menu for SMP/E options (GIM@PRIM), select Query (option 3). This takes you to the initial Query panel. If you need assistance with using the Query dialogs, (or any of the SMP/E dialogs), help panels are available.
5.37 CSI query panel

When the CSI QUERY panel is displayed, you can indicate that you want SMP/E to check target zone MVST600 for all SYSMOD entries.

Because the ENTRY NAME was left blank on the CSI QUERY panel, SMP/E displays another panel (see Figure 5-38 on page 364) that lists all the SYSMOD entries in target zone ZOSTGT1.
5.38 CSI query - Select entry

Because the ENTRY NAME was left blank on the CSI QUERY panel, SMP/E displays another panel, shown in Figure 5-38, which lists all the SYSMOD entries in target zone MVST600.

The CSI QUERY - SELECT ENTRY panel shows the SYSMODs that have been applied to target zone MVST600. If you want more information about the contents of a SYSMOD, you can select that entry by entering an S next to it, and another panel is displayed, as shown in Figure 5-39 on page 365.
5.39 CSI query - SYSMOD entry

This panel displays all relevant information about the SYSMOD ZQ94033. As you can see, this SYSMOD is superseded by UK02460; this means that it is contained in or replaced by the SYSMODs UK02460. A superseded SYSMOD (ZQ94033) is functionally lower than the SYSMOD that superseded it. The SYSMOD ZQ94033 was superseded by SYSMODs UQ96160 and UQ96309 before it was superseded by UK02460.

As you can see, the QUERY dialog panels provide a quick and easy way for you to obtain information about your system.

Note: The CSI QUERY dialog allows a wildcard (pattern) for the entry name specification since SMP/E Version 3 Release 3. A selection list of all entry names that match the specified pattern will be displayed when using a wildcard. Patterns of the form ABC* or *ABC may be specified, where ABC is a string from 0 to 7 characters long.
5.40 Building SMP/E jobs using the dialog

--- SMP/E PRIMARY OPTION MENU ---

0 SETTINGS - Configure settings for the SMP/E dialogs
1 ADMINISTRATION - Administer the SMPCSI contents
2 SYSMOD MANAGEMENT - Receive SYSMODs and HOLDDATA and install SYSMODs
3 QUERY - Display SMPCSI information
4 COMMAND GENERATION - Generate SMP/E commands
5 RECEIVE - Receive SYSMODs, HOLDDATA and support information
6 MIGRATION ASSISTANT - Generate Planning and Migration Reports

0 DESCRIBE - An overview of the dialogs
T TUTORIAL - Details on using the dialogs
W WHAT IS NEW - What is New in SMP/E

Specify the name of the CSI that contains the global zone:
SMPCSI DATA SET ==> 'ZOSR06.GLOBAL.CSI'
(Leave blank for a list of SMPCSI data set names.)

Specify YES to have DD statements for SYSOUT and temporary data sets generated. Specify NO, to use DDDEFs.
Generate DD statements ==> NO

Figure 5-40  Building SMP/E jobs using the dialog

Building SMP/E jobs using the dialog
You can use the SMP/E dialog to generate jobs, for RECEIVE, APPLY, LIST, and so forth.

Suppose that you want to list all PTFs that are RECEIVED for an FMID. In the SMP/E Primary Option Menu, select Option 4, Command Generation. You must also enter the SMPCSI DATA SET field, or enter it on the next displayed panel. If you specify the name of the CSI, you receive the panel shown in Figure 5-40.
5.41 Command generation - Selection menu

Using this panel, SMP/E lists the commands that you can select. To illustrate the use of this panel, we selected option 32, the LIST command, as shown in Figure 5-41.

The SMP/E data sets contain a great deal of information (the global zone, target zones, distribution zones, SMPPTS, SMPLOG, and SMPSCDS) that you may find useful when installing a new function, preparing a user modification, or debugging a problem. You can use the SMP/E LIST command to display that information.

SMP/E can display all the entries of a specified type (such as MOD, MAC, SYSMOD, and so on), or it can display information for selected entries. In addition, for SYSMOD entries, SMP/E provides some additional operands you can specify to list groups of SYSMODs that meet certain criteria.

In the following six figures, we take you through a set of screens that show the generation of a LIST command.
5.42 Command generation - Select zone

Select the zone that is to be processed:
(Enter HELP to view the zone types allowed for each command.)

</tr>
<tr>
<td>Blank to specify multiple entry names.</td>
</tr>
</tbody>
</table>

Specify additional LIST options:

| ALL ZONES  ===> NO                |
| YES to list all zones             |

| XREF OPTION  ===> NO              |
| YES for the XREF option           |

To continue with LIST request, press ENTER.
To cancel this request, enter END.

Figure 5-43  Command generation - LIST command

Command generation - LIST command
As shown in Figure 5-43, we selected ENTRY TYPE=SYSMOD and ENTRY NAME=ALL.

Note: If you leave ENTRY TYPE and ENTRY NAME blank, SMP/E will display a panel with all entry types and will ask you to make a selection.
5.44 Command generation - LIST global zone SYSMOD options

COMMAND GENERATION - LIST GLOBAL ZONE SYSMOD OPTIONS

Enter YES to limit the SYSMODs or MCS to be processed:

FUNCTIONS ===> NO FUNCTION type SYSMODs
PTFs ===> YES PTF type SYSMODs
APARS ===> NO APAR type SYSMODs
USERMODS ===> NO USERMOD type SYSMODs

ERROR ===> NO SYSMODs marked in ERROR

HOLDERROR ===> NO SYSMODs held for HOLDERROR
HOLDSYSTEM ===> NO SYSMODs held for HOLDSYSTEM
HOLDUSER ===> NO SYSMODs held for HOLDUSER

SOURCEID ===> NO SYSMODs for selected SOURCE-IDs
EXSRCID ===> NO SYSMODs without selected SOURCE-IDs
FORFMID ===> YES SYSMODs for selected FMIDs

NOACCEPT ===> NO NO or DLIB zone name
NOAPPLY ===> NO NO or TARGET zone name

To ignore the data entered above and return to previous panel, enter END.

Figure 5-44  Command generation - LIST global zone SYSMOD options

Command generation - LIST global zone SYSMOD options

In the List Global Zone Option, we selected PTFs by entering YES (because we want to list all PTFs that are received) and FORFMID as YES (because we want to restrict the search for only two FMIDs).
5.45 Command generation - List FORFMID

You can select one or more FMIDs in the panel shown in Figure 5-45. When you complete the list of names of FMIDs or FMIDSETs, enter END on the command line.
5.46 Command generation - Selection menu

COMMAND GENERATION SELECTION MENU

To make additional selections enter selection and press ENTER
To EDIT, BROWSE, or SUBMIT generated jobs enter the END command
To leave without submitting any job enter the CANCEL command

The LIST command was created based on your input

Figure 5-46 Command generation - Selection menu

Command generation - Selection menu

After you finish your selection, SMP/E will issue the message The LIST command was created based on your input, as shown in Figure 5-46.

Now, the job that you want is generated by SMP/E. If you want any other service of SMP/E, you can go to the panel again and select another command. The second command will be generated in the same job as the previous one. When you do not have any other changes to make, enter END on the command line.
5.47 Command generation - SUBMIT

Command generation - SUBMIT

After you issue the END command, the panel shown in Figure 5-47 is displayed.

In this panel you can edit the job, option E, or submit the job, option S. When you submit the job, the job executes and you can then browse the output to obtain the information you requested.
5.48 The generated job

Figure 5-48 The generated job

The generated job

Figure 5-48 shows the job generated by SMP/E; you can submit it and it will execute the commands that you chose.

This is the end of our LIST command example.
5.49 Java archive (JAR) file support

Figure 5-49 Java ARchive (JAR) file support

- **SMP/E will provide support for both**
  - **JAR replacement files**
    - complete replacement for a JAR file
    - constructed in JAR file format
    - treated very much like all other ++hfs elements
    - ++JAR
  - **JAR update files**
    - contain only new and changed component files
    - constructed in JAR file format
    - use jar command to 'extract' the component files from a JAR update file and to 'update' a JAR file with the component files
    - ++JARUPD

Java archive (JAR) file support

There are element types to describe JAR files and SMP/E will replace and update such files. The ++JAR element type is used to add and replace entire JAR files and the ++JARUPD element type is used to provide an update for a JAR file. To update a JAR file, SMP/E will add or replace component files within a Java Archive, rather than replacing the entire Java Archive file. This allows for much smaller and more granular PTFs for products that use Java and JAR files. JAR files reside in directories within the UNIX file system, and SMP/E will use the Java `jar` command to update a JAR file when processing a ++JARUPD element.

The JAR file format is based on the popular ZIP file format and is used for aggregating many files into one. Although JAR can be used as a general archiving tool, the primary motivation for its development was so that Java applets and their requisite components (.class files, images, and sounds) can be downloaded to a browser in a single HTTP transaction, rather than opening a new connection for each piece. This greatly improves the speed with which an applet can be loaded onto a Web page and begin functioning. The JAR format also supports compression, which reduces the size of the file and improves download time still further. These attributes make the JAR file format the preferred method to bundle Java applets and applications.

Fundamental operations on a JAR file are performed using the Java Archive Tool provided as part of the Java Development Kit (JDK™). The Java Archive Tool is invoked using the `jar` command. The `jar` command is used to create JAR files, view and extract the contents of JAR files, and update the contents of JAR files. To update the contents of a JAR file means to replace a subset of the files within the archive, add additional files to the archive, or both.
5.50 GIMZIP and GIMUNZIP service routines

GIMZIP packaging service routine

The GIMZIP service routine creates portable packages of software and associated materials. Typically the packages will contain SYSMODs, RELFILE data sets, HOLDDATA, and associated materials such as documentation, samples, and text files. These GIMZIP packages can be transported through a network, processed by the GIMUNZIP service routine, and then processed by the SMP/E RECEIVE command. A single GIMZIP package typically consists of several archive files. More specifically, a GIMZIP package consists of a single package definition file, a set of archive files, and text files. The package definition file describes the total package and identifies the archive files and text files contained in the package. The GIMZIP package file produced is stored in the package directory in a UNIX file system. The package directory is specified by the SMPDIR DD statement. The GIMZIP service routine processes the following data structures as input to create GIMZIP packages:

- A portable image of any of the following:
  - Sequential data set
  - Partitioned data set
  - VSAM data set
  - A file in the UNIX file system
  - A directory in the UNIX file system

- The information necessary to reload the data from the portable image

GIMZIP collects various attributes for the input data sets and files specified in the package control tags. These attributes, along with portable images of the input data sets, are
temporarily stored in a UNIX file system. These images are then archived and compressed to create archive files. Each GIMZIP package will contain one or more archive files.

For each package there are two additional files:

- **The package attribute file**, which describes the contents of the package itself. The package attribute file identifies the archives for a package and contains a hash value for each archive within the package. The hash value for each archive is used for data integrity purposes and can be checked when the original data set is re-created from the archive using the GIMUNZIP service routine.

- **An extensible stylesheet language (XSL) file**, which describes how to format the information found in the package attribute file. The XSL file is used for rendering (displaying on a browser) the package attribute file.

### Archive files

The actual software and associated materials for a package are stored in archive files. GIMZIP creates an archive file for each input data set or file specified by a `<FILEDEF>` tag. An archive file consists of a portable image of the original data set or file and attributes of the original data set or file needed to reload the data from the portable image.

The attributes of the original data set or file are recorded in a file attribute file in the UNIX file system called GIMFAF.XML. For data sets, the portable image of the original data set is stored temporarily as a file in the UNIX file system (this step is not required for UNIX files and directories). The name of this temporary file is the type attribute value for the archive (SMPPTFIN, SMPHOLD, SMPRELF) or the name MVSFILE if the archive has no type attribute specified. An archive file is then created by using the UNIX System Services `pax` command to combine the GIMFAF.XML file and the original data into an archive. Although a UNIX file is not first stored as a temporary file with a name matching its type attribute value, its name within the archive will be its type attribute value, or the name MVSFILE, if the archive has no type attribute specified. The GIMUNZIP service routine and the RECEIVE command both expect an archive file to contain the GIMFAF.XML component file, and the following, depending on the original content:

- For data sets, a file named SMPPTFIN, SMPHOLD, SMPRELF, or MVSFILE.
- For UNIX, files named SMPPTFIN, SMPHOLD, or MVSFILE.
- For UNIX directories, the directory and its contents are stored in the archive using the original names.

Data sets and files with a type of README are an exception to the previously described archive processing. README data sets and files have no file attribute file and are not archived using `pax`, but rather are stored unchanged in a file in the package directory. Likewise, README data sets and files are not subject to archive segmentation.

The absolute names for archive file and README files in the package directory use the following format: `/package_directory/subdir/Snnnn.original__name.pax.Z`

The absolute names for archive segment files in the package directory use the following format: `/package_directory/subdir/date_timeofday.nofm`

- `package_directory` indicates the package directory specified on the SMPDIR DD statement.
- `subdir` indicates the subdirectory into which the archive file is stored. GIMZIP creates this subdirectory based on the filetype or the subdir attributes specified on the `<FILEDEF>` tag for the data set. If neither attribute is specified, then no subdirectory is used. If the file type is README, the subdirectory is created only if the subdir attribute has been specified.
specifies the sequence indicator for the archive file. The sequence indicator is necessary so the correct order can be determined for the SMPHOLD and SMPPTFIN files when eventually processed by the SMP/E RECEIVE command. GIMZIP processes the input data sets or files in the sequence in which they are specified in the package control tags and the indicator is assigned accordingly. All archive files, except those specified with a file type of SMPREL, are assigned a sequence indicator. If the file type is README and an archid tag was specified, then no sequence number will be assigned.

original_name specifies the original name of the data set, file, or directory, as indicated on the <FILEDEF> tag. This could also be the archid for UNIX directories and README data sets or files, or the date and time for UNIX directories, if the archid is not specified.

pax.Z is the file extension for all archive files, except those with a file type of README. The pax.Z extension indicates a file that has been processed by the UNIX System Services pax command with the compress option.

date_timeofday is the date and time of day value, unique for each archive, but the same for each segment file of a particular archive.

n is the segment number.

m is the total number of segments for the archive.

Note: Since SMP/E Version 3 Release 2, large archive files within GIMZIP packages may be divided into smaller segments. The GIMZIP Service Routine has a new SEGMENT option to allow you to specify the maximum desired size of archive segment files in megabytes. GIMZIP will then divide large archives into multiple smaller physical files, thus enabling more efficient network transport and retry operations on the packages. GIMUNZIP service routines have been updated to support processing of packages with segmented archive files.

File Attribute File
The File Attribute File (FAF) is included in the archive file along with the data set, file, or directory when it is archived. The FAF contains control tags that:

- Describe the attributes of the original data set, file, or directory
- Provide information needed by GIMUNZIP to process the archive

Example of using GIMZIP
Suppose a GIMZIP package is to be created containing the following data sets, files, and directories:

/SAMPLE/ORDER123/readme.html - a README file
/SAMPLE/ORDER123/SMPMCS - an SMP/E MCS file
SAMPLE.IBM.FMID001.F1 - an SMP/E PDS relative file
SAMPLE.IBM.FMID001.F2 - an SMP/E PDSE relative file
SAMPLE.ORDER123.DOCLIB - a PDS containing documents
SAMPLE.ORDER123.RIMLIB - a PDS containing related installation materials
SAMPLE.ORDER123.MVS.GLOBAL.CSI - a VSAM cluster
/SAMPLE/ORDER123/RootHFS/ - the root directory

The job stream on Figure 5-51 can be used to create such a GIMZIP package. This package directory resides in the UNIX file system and it specified by the SMPDIR DD statement. The package directory name is:

'/'u/smpe/GIMZIP/ORDER123/''
//JOBx JOB...
//STEP1 EXEC PGM=GIMZIP,PARM='SEGMENT=12M'
//SMPDIR DD PATH='/u/smpe/GIMZIP/ORDER123/',PATHDISP=KEEP
//SMPOUT DD SYSOUT=* 
//SYSPRINT DD SYSOUT=* 
//SYSUT2 DD UNIT=SYSALLDA,SPACE=(CYL,(200,20))
//SYSUT3 DD UNIT=SYSALLDA,SPACE=(CYL,(50,10))
//SYSUT4 DD UNIT=SYSALLDA,SPACE=(CYL,(25,5))
//SYSIN DD *

<GIMZIP
description="This is a sample software package.">
<FILEDEF name="/SAMPLE/ORDER123/readme.html"
archid="readme.html"
description="This is the README file for the package." 
subdir="README"
type="README">
</FILEDEF>

</GIMZIP>

Figure 5-51  GIMZIP sample job

Note: For more information about the GIMZIP service routine, see SMP/E Reference, SA22-7772.
GIMUNZIP uses the UNIX System Services `pax` command to expand the following component files from an archive file temporarily into a UNIX file system:

- The portable image of the original data set or file
- The file attribute file that contains the information necessary to reload the data from the archived data set or file

GIMUNZIP then reads the file attribute file and uses the information recorded there, along with information specified on the `<ARCHDEF>` tag, such as volume, newname, or prefix, to allocate a new or existing data set or file. The portable image of the original data set or file is stored in the data set or file just allocated for that purpose.

When GIMUNZIP encounters a package that contains archive segments, GIMUNZIP reassembles the archive segments into the original archive form, optionally verifies the integrity of the archive, and recreates the original data.

If the HASH=YES option was specified, then GIMUNZIP performs SHA-1 hash checking for the archive files. Specifically, GIMUNZIP reads the package attribute file for the package. The package attribute file, GIMPAMF.XML, is found in the package directory, and contains the known hash values for the archives. These hash values were recorded by GIMZIP when the package and archives were created. GIMUNZIP then uses ICSF services to compute the current hash values for the archive files, and compares this value to the known hash values for the archive files.

If the computed hash value matches the known hash value, then the integrity of the archive file is ensured. However, if the computed hash value does not match the known hash value, GIMUNZIP processing stops. This condition indicates the archive file has been corrupted since it was produced by GIMZIP when the package was created.

**Example of using GIMUNZIP**

Suppose a GIMZIP package contains a set of archive files and you want to extract the data sets and files from those archive files. In addition, you wish to verify the integrity of the archive files and rename the destination data sets and files in the process. The job stream in Figure 5-52 on page 381 can be used to perform such an operation.
SMP/E Version 3 Release 1 can receive input from a network server, in addition to tape and DASD. This enables the delivery of SMP/E-installable products and service over the internet or an intranet. By installing software directly from a network source, SMP/E enables a more seamless integration of electronic software delivery and installation. This reduces the tasks and time required to install software delivered electronically.

SMP/E provides the GIMZIP and GIMUNZIP service routines to construct, and then later unwrap, network transportable packages of software. Specifically, the GIMZIP service routine will create a network transportable package as output. Once a package is made accessible on an FTP server, you can use the SMP/E RECEIVE command to transfer the package through a TCP/IP network directly into an SMP/E environment.

The RECEIVE command has been extended with new DELETEPKG, FROMNETWORK, and FROMNTS operands to process these network transportable packages. In SMP/E Version 3 Release 2 or z/OS V1R5, the RECEIVE FROMNETWORK and FROMNTS commands have been updated to support processing of packages with segmented archive files and subdirectories that may be produced by GIMZIP. SMP/E releases prior to SMP/E V3R2 cannot process GIMZIP output that contains segmented archive files. A toleration PTF will
issue an error message should a user try to process GIMZIP output that contains segmented archive files on a release of SMP/E prior to V3R2. For more information on the RECEIVE command changes, see SMP/E Commands, SA22-7771.

New CLIENT and SERVER data sets and SMPDIR and SMPNTS directories have been created to support this new processing. For more information on CLIENT, SERVER, SMPDIR, and SMPNTS, see SMP/E Reference, SA22-7772.

Following is a sample RECEIVE job that would process the SMPMCS and RELFILE data sets and files extracted by GIMUNZIP in the example shown in Figure 5-52.

```bash
//JOBx JOB...
//STEP1 EXEC PGM=GIMSMP
//SMPCSI DD DSN=SMPE.GLOBAL.CSI,DISP=SHR
//SMPPTFIN DD DSN=USERID.FMID001.SMPMCS,DISP=SHR
//SMPCNTL DD *
SET BDY(GLOBAL).
RECEIVE SYSMODS
   RFPREFIX(USERID).
/*
5.51 GIMXSID service routine

GIMXSID is an SMP/E service routine to be used as part of the ShopzSeries offering. GIMXSID creates a single data source required by ShopzSeries to place customized software product and service orders. The data source created by GIMXSID, the software inventory data, is a composite of three kinds of information as follows:

- **Feature List**
  List of FEATUREs found in the SMPCSI data sets. The Feature List is used by ShopzSeries to perform product requisite checking and also to prime the order checklist when ordering a ServerPac.

- **FMID List**
  A list of the FMIDs found in the SMPCSI data sets. The FMID List is used by ShopzSeries to scope service orders to the PTFs applicable solely to the user's desired configuration of target and global zones.

- **PTF Bitmap**
  Bitmap representation of the PTFs found in the specified target zones and global zones. The PTF Bitmap is used by ShopzSeries to produce service packages that do not contain PTFs that are already present in the user's configuration.

GIMXSID is an independent load module residing in the MIGLIB library. GIMXSID runs independently from the rest of SMP/E processing.
The service routine, GIMXSID, is used to simplify and consolidate the data collection tasks necessary to place ShopzSeries software product and service orders. GIMXSID can be used to collect the software inventory product (FEATURE) and service (FMID and PTF) information for specified target zones, and in one or more global zones.

ShopzSeries provides a self-service planning and ordering capability on the Web. You can order system/product upgrades for either ServerPac or CBPDO. ShopzSeries includes the following significant functions:

- Profiling of the checklist. ShopzSeries will analyze and prefill the order checklist when you submit your existing installed inventory to the tool.
- Full automation to process orders that do not require license changes. Orders that include new or changed licenses will be routed to the IBM Sales Center.
- Access to software inventory reports through the Customer Analysis Tool.
- Ordering of service-only CBPDOS.

ShopzSeries support for maintenance includes ordering corrective service by PTFs or APARs and Recommended Service Upgrade (RSU) preventive service. In addition, service orders can be received on traditional media or via the Internet. For an RSU order, you can upload your SMP/E CSI installed service inventory, which is used to customize your order and eliminate duplicate service.

Figure 5-54 shows a sample of how to use GIMXSID. In this example, the ZOS14 and JES314 target zones are processed from the global zone in the SMPE.ZOSREAL.GLOBAL.CSI data set. In addition, all target zones from the global zone in the SMPE.DB2REAL.GLOBAL.CSI data set are processed. The software inventory output can be written to a data set or to a file in the UNIX file system.

```
//job     JOB ...
//BITMAP   EXEC PGM=GIMXSID
//SMPOUT   DD SYSOUT=*  
//SMXTOUT  DD DSN=userid.GIMXSID.OUTPUT,DISP=(NEW,CATLG),
//           SPACE=(TRK,(1,1)),UNIT=SYSALLDA
//SYSIN    DD *
CSI=SMPE.ZOSREAL.GLOBAL.CSI
TARGET=ZOS14,JES314
CSI=SMPE.DB2REAL.GLOBAL.CSI
/*
```

Figure 5-54  GIMXSID sample JCL

**GIMUNZIP file extraction service routine**

The GIMUNZIP service routine is used to extract data sets, files, and directories from archive files in GIMZIP packages created by the GIMZIP service routine. These packages typically contain software and associated materials in the form of SYSMODs, RELFILE data sets, HOLDDATA, and other materials such as documentation, samples, and text files. These GIMZIP packages may be transported through a network, processed by the GIMUNZIP service routine, and then processed by the SMP/E RECEIVE command. More specifically, the GIMUNZIP service routine extracts data sets, files, and directories from the archive files that compose the GIMZIP package. An archive file consists of a portable image of a sequential, partitioned, or VSAM data set, or a file or directory in a UNIX file system, and the information needed to create that data set, file, or directory from the portable image. The data set, file, or directory into which the archive file is to be extracted can already exist or GIMUNZIP can create a new one of the appropriate type. New sequential and partitioned data sets created by GIMUNZIP are always catalogued.
Language Environment

This chapter introduces you to the Language Environment architecture, a set of constructs and interfaces that provides a common run-time environment and run-time services for all Language Environment-conforming programming language products (those products that adhere to Language Environment's common interface).

This chapter contains an overview of Language Environment, descriptions of Language Environment's full program model, callable services, storage management model, and debug information.

Language Environment provides a common run-time environment for IBM versions of certain high-level languages (HLLs), namely, C, C++, COBOL, Fortran, and PL/I, in which you can run existing applications written in previous versions of these languages as well as in the current Language Environment-conforming versions, without having to recompile or relink-edit the applications. Prior to Language Environment, each of the HLLs had to provide a separate run-time environment. POSIX-conforming C applications can use all Language Environment services.

Language Environment combines essential and commonly used run-time services, such as routines for run-time message handling, condition handling, storage management, date and time services, and math functions, and makes them available through a set of interfaces that are consistent across programming languages. With Language Environment, you can use one run-time environment for your applications, regardless of the application's programming language or system resource needs, because most system dependencies have been removed.
6.1 Language Environment (LE)

Language Environment

Today, enterprises need efficient, consistent, and less complex ways to develop quality applications software and to maintain their existing inventory of applications. The trend in application development is to create modules and share code. Language Environment gives you a common environment for all Language Environment-conforming high-level language (HLL) products. See “High-level language and programs” on page 390.

In the past, programming languages also had limited ability to call each other and behave consistently across different operating systems. This has constrained those who wanted to use several languages in an application. Programming languages have had different rules for implementing data structures and condition handling, and for interfacing with system services and library routines.

Figure 6-1 lists the topics covered in this chapter.
6.2 Assembler language and programs

Assembler language

A computer can understand and interpret only machine language instructions. Machine language is in binary form and, thus, is very difficult to write. The assembler language is a symbolic programming language that you can use to code instructions in a mnemonic format instead of coding in machine language in binary format.

Assembler language lets you use meaningful symbols made up of alphabetic and numeric characters, instead of just the binary digits 0 and 1 used in machine language instructions. This makes your coding easier to read, understand, and change. Assembler is also enriched by a huge set of macros that make it a very powerful language; however, its major quality is the performance of its object code at run time.

One of the key aspects of a computer language is its readability and capacity to document itself. This aspect is mandatory in a commercial environment, where applications should last for many years (to justify the investment). Longevity of an application means that different generations of programmers will be in charge of writing and maintaining the code, which implies that readability is a required quality of the language. Certain modern languages like C do not follow this rule. However, if you write an assembler program using all the documenting capability of its features, chances are that you will produce more readable code than some HLLs allow.

The assembler must translate the symbolic assembler language you wrote into machine language before the computer can run your program. The specific procedures followed to do
this vary according to the operating system you are using. However, the method is basically the same and consists of the following:

Your program, written in the assembler language, becomes the source module that is input to the assembler program. The assembler processes your source module and produces an object module in machine language (called object code). The object module can be used as input to be processed by the binder. The binder produces a load module that can be loaded later into the main storage of the computer. When your program is loaded, it can then be run. Your source module and the object code produced are printed, along with other information, on a program listing.

Using assembler language
The assembler language is the symbolic programming language that lies closest to the machine language in form and content. You will, therefore, find the assembler language useful when:

- You need to control your program closely, down to the byte level and even to the bit level.
- You must write subroutines for functions that are not provided by other high-level programming languages, such as COBOL, FORTRAN, or PL/I.
- You need good performance at execution time.

The assembler language is made up of statements that represent either instructions or comments. The instruction statements are the working part of the language and are divided into the following three groups:

- Machine instructions
  A machine instruction is the symbolic representation of a machine language instruction. It is called a machine instruction because the assembler translates it (one-to-one) into the machine language code that the computer can run.

- Assembler instructions
  An assembler instruction is a request to the assembler to do certain operations during the assembly of a source module; for example, defining data constants, reserving storage areas, and defining the end of the source module. Except for the instructions that define constants, and the instruction used to generate no-operation instructions for alignment, the Assembler does not translate assembler instructions into object code.

- Macro instructions
  A macro instruction is a request to the assembler program to process a predefined sequence of instructions called a macro definition. From this definition, the Assembler generates machine and assembler instructions, which it then processes as if they were part of the original input in the source module.

IBM supplies macro definitions for input/output, data management, and supervisor operations that you can call for processing by coding the required macro instruction.

You can also prepare your own macro definitions, and call them by coding the corresponding macro instructions. Rather than code all of this sequence each time it is needed, you can create a macro instruction to represent the sequence and then, each time the sequence is needed, simply code the macro instruction statement. During assembly, the sequence of instructions represented by the macro instruction is inserted into the source program.

Assembler program relationship to z/OS
The assembler program, also referred to as the assembler, processes: the machine, assembler instructions, and macro instructions you have coded (source statements) in the assembler language, and produces an object module in machine language.
The assembler in z/OS is called High Level Assembler. z/OS provides the assembler with services for:

- Assembling a source module
- Running the assembled object module (after being link-edited) as a program

In writing a source module, you must include instructions that request any required service functions from z/OS.

z/OS provides the following services:

- For assembling the source module:
  - A control program
  - Sequential data sets to contain source code
  - Libraries to contain source code and macro definitions
  - Utilities
- For preparing the execution of the Assembler program as represented by the object module:
  - A control program
  - Storage allocation
  - Input and output facilities

It can be very difficult to write an assembler language program using only machine instructions. The assembler provides additional functions, not discussed here, that make this task easier.

The assembler-generated object module must be link-edited by the Binder utility program to be transformed into an executable program. This executable program is called a load module when it is stored in a PDS library, and a program object when it is stored in a PDSE.
6.3 High-level language and programs

A high-level language (HLL) is a *programming language* above the level of assembler language and below that of program generators and query languages. The statements created in one of these languages can be the input to a computer program called a *compiler* that translates the HLL statements in machine language instructions, *object code*. It has instructions recognized by the processor of the specific platform where it is supposed to be executed. This object code is the fabric of the executable program, also called the *load module* or *program object*.

When we refer to high-level language in this chapter, we are referring to any of the following:

- C or C++
- COBOL
- FORTRAN
- PL/I
6.4 Creating execution programs

- In the sixties almost all the instructions were generated in the compilation and included in the object module.
- In the seventies lots of pre-compiled common functions were included during the link-edit of the object module.
- Currently lots of pre link-edit load modules are called dynamically (through Link, XCTL interfaces) from run-time libraries during execution.
- Language Environment makes extensive use of run-time libraries to create a common behavior among several high-level languages.

Creating execution programs - an evolution

In the sixties, the object module created from the source by the HLL compiler or by the assembler had all the machine code instructions, as declared in the source. Logically, the only code missing in the object module was the operating system instructions needed to execute certain functions such as an I/O operation. In this case the compiler (or the assembler) generated an API call that at execution time would call the operating system for the required function.

In the seventies, we had the first revolution in these matters. In order to reduce the cost, increase the speed, and simplify the construction of compilers, the concept of pre-compiled routines was introduced. Then, together with the compiler code, IBM sent lots of object modules kept in libraries. These object modules had the logic of: data format convention, arithmetic functions, preparing an I/O request to be executed, and so on. When the compiler needed one of these routines it just made an external call to an existing object module. Later, when the Binder link-edited the source, those mentioned object modules were naturally included, making just one load module.

Finally, in the nineties the last revolution occurred. The pre-compiled object modules are replaced by pre link-edited load modules stored in run-time libraries sent with compile code. The external calls generated by the compilers are replaced by APIs that dynamically, through z/OS program management functions (as such LINK and XCTL), load and pass the CPU control to such load modules.
There are a few technical justification for such an implementation:

- The load module generated from the compilation is small (compared with the previous method) and, recalling that in a commercial program only 20% of the code (kernel) is executed frequently, we are saving virtual and central storage. However, there is a performance issue because when a needed function is implemented in a load module stored in a run-time library, an I/O operation (with an implicit wait) is needed during the task execution. LLA and VLF can be used to minimize this effect.

- Compiler manufacturers such as IBM can write common load modules for usual functions, such as: message handling, condition handling, program storage management, date and time services, math functions, abnormal termination, and others. Those load modules can be available in run-time libraries being shared and consistent across different programming languages, such as: Cobol, PL/1, Fortran, C, C++. For the customer, the advantage is to have the same behavior for a program independent of the language used. Also, it is much easier for a program written in Cobol to make a call to another in C.

For the manufacturer the cost of writing and maintaining different languages is much less.

The last revolution created the structure for IBM to implementing Language Environment. LE uses run-time libraries for dynamic load of common load modules, but also uses common Syslibs, including shared object modules, during Binder link-edit.

So, restating the LE definition: “Language Environment provides a common run-time environment for IBM versions of certain high-level languages (HLLs), namely, C, C++, COBOL, Fortran, and PL/I, in which you can run existing applications written in previous versions of these languages, as well as in the current Language Environment-conforming versions, without having to recompile or re-link-edit the applications. Prior to Language Environment, each of the HLLs had to provide a separate run-time environment. POSIX-conforming C applications can use all Language Environment services”
6.5  IBM compiler products and LE

- z/OS C/C++
- C/C++ Compiler for MVS/ESA(TM)
- AD/Cycle® C/370(TM) Compiler
- VisualAge for Java, Enterprise Edition for OS/390
- Enterprise COBOL for z/OS and OS/390
- COBOL for OS/390 & VM
- COBOL for MVS & VM (formerly COBOL/370)
- Enterprise PL/1 for z/OS and OS/390
- VisualAge PL/I for OS/390
- PL/I for MVS & VM
- AD/Cycle PL/I for MVS & VM
- VS FORTRAN and FORTRAN IV (in compatibility mode)

Figure 6-5  IBM compiler products and LE

IBM compiler products and LE

z/OS Language Environment is the prerequisite run-time environment for applications generated with the IBM compiler products shown in Figure 6-5.

IBM Enterprise COBOL for z/OS is IBM’s strategic COBOL compiler for the zSeries platform. Enterprise COBOL is comprised of features from IBM COBOL, VS COBOL II, and OS/VS COBOL, with additional features such as multithread enablement, Unicode, XML capabilities, object-oriented COBOL syntax for Java interoperability, integrated CICS translator, and integrated DB2 coprocessor (zIIP). Enterprise COBOL, as well as IBM COBOL and VS COBOL II, supports the COBOL 85 Standard. Some features, such as the CMPR2 compiler option and SOM-based object-oriented COBOL syntax that IBM COBOL supported are no longer available with Enterprise COBOL.

Language Environment provides a single language run-time environment for COBOL, PL/I, C, and FORTRAN. In addition to support for existing applications, Language Environment also provides common condition handling, improved interlanguage communication (ILC), reusable libraries, and more efficient application development. Application development is simplified by the use of common conventions, common run-time facilities, and a set of shared callable services. Language Environment is required to run Enterprise COBOL programs.

In many cases, you can run compiled code generated from the previous versions of these compilers. A set of assembler macros is also provided to allow assembler routines to run with Language Environment.
6.6 LE standards

- C is the HLL of the open world
- Standards committees and products:
  - IEEE with Portable Operating System Interface (POSIX)
  - XPG, a set of companies for computer standards
  - ISO/IEC
- z/OS and Language Environment conforms to:
  - POSIX 1003.1
  - XPG4.2 SPEC 1170
  - ISO/IEC 9945

Figure 6-6  LE standards

LE standards
The UNIX market is very competitive, so each software house adds other functions to the kernel. This creates “UNIX proprietary” code. To address the problem, standards like Portable Operating System Interface (POSIX) were introduced to define standard interfaces based on UNIX.

The IEEE POSIX standard is a series of industry standards for code and user interface portability. The UNIX System Services component in z/OS conforms with POSIX, so applications written for a UNIX-like operating system can run on z/OS. z/OS systems’ UNIX System Services is also branded “UNIX by X/Open committee.” C language programs can access operating system services through a set of standard language bindings. Programs written in C, due to UNIX System Services and z/OS Language Environment, can call C language functions defined in the POSIX standard from their C applications. Also they can run applications that conform to ISO/IEC 9945-1:1990 and conform to XPG4.2 specifications.

Applications that call POSIX functions can perform limited Interlanguage Communication (ILC) under Language Environment (see z/OS Language Environment Writing Interlanguage Communication Applications, SA22-7563, for details). In addition, C POSIX-conforming applications can use all Language Environment services.
6.7 LE components

Figure 6-7  LE components

Language Environment consists of:

- **Basic routines** that support starting and stopping programs, allocating storage, communicating with programs written in different languages, and indicating and handling conditions.

- **Common library** includes common services, such as messages, date and time functions, math functions, applications utilities, system services, and subsystem support, that are commonly needed by programs running on the system. These functions are supported through a library of callable services.

- **Language-specific portions of the run-time library** because many language-specific routines call Language Environment services. However, behavior is consistent across languages.

POSIX support is provided in the Language Environment base and in the C language-specific library.

**Note:** With AMODE 64 only the z/OS C/C++ language-specific portion of the run-time library is available.
6.8 LE common run-time environment

**Figure 6-8 LE common run-time environment**

**LE run-time environment**

Figure 6-8 illustrates the common environment that Language Environment creates. It also shows that each HLL has its specific run time (for load modules) and SYSLIB (for object modules), and shares with other HLLs a Common Execution Library (CEL). Figure 6-8 further shows that the load modules produced in this way can be executed in different operating environments under z/OS, VSE and z/VM®.
6.9 LE run-time environment for AMODE 64

**Figure 6-9** LE common run-time environment for AMODE 64

**Run-time for AMODE 64**

Figure 6-9 illustrates the common environment that Language Environment AMODE 64 creates. It also shows that the load modules produced in this way can be executed only under z/OS. Those load modules are loaded below the bar (2-G) but may access addresses above such bar.

In the 64-bit addressing mode (AMODE 64) supported by Language Environment, addresses are 64 bits in length, which allows access to virtual storage up to 16 exabytes. While this is an extremely high address, there are a few very important facts to consider:

- Existing or new Language Environment applications that use AMODE 24 or AMODE 31 can continue to run without change. They run using the same Language Environment services that existed before 64-bit addressing was introduced, and these services will continue to be supported and enhanced.

- Language Environment applications that use AMODE 64 are not compatible with applications that use AMODE 24 or AMODE 31. The only means of communication between AMODE 64 and AMODE 24 or AMODE 31 applications is through mechanisms that can communicate across processes or address spaces. However, Language Environment applications that use AMODE 64 can run with existing applications that use AMODE 24 or AMODE 31 on the same physical zSeries system.

- Where necessary, there are new Language Environment run-time options to support AMODE 64 applications. The new run-time options primarily support the new stack and
heap storage located above the bar. All other existing run-time options continue to be supported and enhanced for AMODE 24 and AMODE 31 applications.

The z/OS C/C++ compiler with the LP64 compiler option is the IBM Language Environment-conforming language compiler that currently supports 64-bit addressing.

Along with the change in addressing mode to use 64 bits, the other important consideration is that long data types also use 64 bits. The industry standard name for this data model is LP64, which translates roughly to “long and pointer data types use 64 bits.” The Language Environment support for AMODE 24 and AMODE 31 applications is ILP32, meaning “integer, long, and pointer data types use 32 bits.”

Language Environment also provides new assembler macros that support creating Language Environment-conforming assembler applications that run AMODE 64.

**Note:** Language Environment-conforming AMODE 64 applications cannot run on any release prior to z/OS Version 1 Release 6.
6.10 Object code and LE

- The object code is included in the load module in three different times in z/OS:
  - At compile time
  - At binder time
  - At execution time

- LE run time environment
  - Libraries that contain code

- HLL and LE
  - Common run time environment (for load modules at execution time)
  - Common set of SYSLIB libraries (for object modules at Binder time)

Object code and LE

The object code is included in the load module at three different times in z/OS:

- At compile time.
- At binder time, through the INCLUDE statement or resolving external references from the SYSLIB library.
- At execution time, through MVS dynamic link macros such as LINK and LOAD, which fetch to memory, or code from the load modules library. This approach is also called late binding.

The libraries containing the code invoked dynamically are called the run-time environment. Language Environment establishes a common run-time environment plus a common set of the SYSLIB libraries for all participating HLLs. However, due to many language-specific functions, there is still a need of some language-specific libraries as C/C++, COBOL, FORTRAN, PL/I.
6.11 Callable services

LE callable services

- Communicating conditions services
- Condition handling services
- Date and time services
- Dynamic storage services
- General callable services
- Initialization/termination services
- Locale callable services
- Math services
- Message handling services
- National language support services

Figure 6-11 Language environment callable services

Callable services

Language Environment helps you create mixed-language applications and gives you a consistent method of accessing common, frequently used services. Building mixed-language applications is easier with Language Environment-conforming routines because Language Environment establishes a consistent environment for all languages in the application.

Language Environment provides the base for future IBM language library enhancements in the z/OS environment.

Because Language Environment provides a common library, with services that you can call through a common callable interface, the behavior of your applications will be easier to predict. However, you do not need to call specifically such services, they are automatically included in your program depending on the statements you use in your HLL source code. Language Environment’s common library includes common services such as messages, date and time functions, math functions, application utilities, system services, and subsystem support. The language-specific portions of Language Environment provide language interfaces and specific services that are supported for each individual language.

The following example illustrates how to invoke a Language Environment service in COBOL for z/OS:

```
CALL "CEEFMDT" USING COUNTRY, PICSTR, FC.
```

You should use a CALL statement with the correct parameters for that particular service. See z/OS Language Environment Programming Guide, SA22-7561, for details.
The language-specific portions of Language Environment provide language interfaces and specific services that are supported for each individual language. Language Environment is accessed through defined common calling conventions.

**Note:** The callable services mentioned in Figure 6-11 on page 400 are for AMODE 31 only. For AMODE 64, none of the application writer interfaces (AWIs) will be supported in their present form. There may be C functions that provide similar functionality for some of the AWIs. A few non-standard C functions have been added to provide the functionality of some of the AWIs. See *z/OS C/C++ Run-Time Library Reference-SA*, SA22-7821, for details.
6.12 LE program management terms and terminology

- **General programming terms**
  - Application program
  - Environment

- **Terms and their HLL equivalents**
  - Routine
  - Enclave
  - Process
  - Thread

- **Terminology for data**
  - Automatic
  - External
  - Local

**Program management**

The Language Environment program management model provides a framework within which an application runs. It is the foundation of all of the component models — condition handling, run-time message handling, and storage management — that comprise the Language Environment architecture. The program management model defines the effects of programming language semantics in mixed-language applications and integrates transaction processing and multithreading.

Some terms used to describe the program management model are common programming terms; other terms are described differently in other languages. It is important that you understand the meaning of the terminology in a Language Environment context as compared to other contexts.

**General programming terms**

Following are some general programming terms:

- Application program
  - A collection of one or more programs cooperating to achieve particular objectives such as inventory control or payroll.

- Environment
  - In Language Environment, normally a reference to the run-time environment of HLLs at the enclave level.
LE terms and HLL equivalents

Following are some LE terms and HLL equivalents:

- **Routine**
  
  In Language Environment, this refers to either a procedure, function, or subroutine.
  
  Equivalent HLL terms: COBOL - program; C/C++ - function; PL/I - procedure, BEGIN block.

- **Enclave**
  
  In Language Environment, a collection of routines, one of which is named as the main routine. The enclave contains at least one thread.
  
  Equivalent HLL terms: COBOL - run unit; C/C++ - program, consisting of a main C function and its sub-functions; PL/I - main procedure and its subroutines; FORTRAN - program and its subroutines.

- **Process**
  
  The highest level of the Language Environment program management model. A process is a collection of resources, both program code and data, and consists of at least one enclave.

- **Thread**
  
  An execution construct that consists of synchronous invocations and terminations of routines. The thread is the basic run-time path within the Language Environment program management model, and is dispatched by the system with its own run-time stack, instruction counter, and registers. Threads may exist concurrently with other threads.

Terminology for data

The following terminology describes the types of data used in an LE environment:

- **Automatic data**
  
  Data that is allocated with the same value on entry and re-entry into a routine if it has been initialized to that value in the semantics of the language used. The data does not persist across calls. The scope of automatic data is a routine invocation within an enclave.

- **External data**
  
  Data that persists over the lifetime of an enclave and retains last-used values whenever a routine is re-entered. The scope of external data is that of the enclosing enclave; all routines invoked within the enclave recognize the external data.

- **Local data**
  
  The scope of local data is that of the enclosing enclave; however, local data is recognized only by the routine that defines it.

  Equivalent HLL terms: C/C++ - local data; COBOL - WORKING-STORAGE data items and LOCAL-STORAGE data items; PL/I - data declared with the PL/I INTERNAL attribute.
6.13 LE program management model

Figure 6-13 LE program management

Program management model

Three entities — process, enclave, and thread — are at the core of the Language Environment program management model.

Figure 6-13 shows the relationship between processes, enclaves, and threads. It illustrates the simplest form of the Language Environment program management model and how resources such as storage are managed.

Process

A process is the highest level component of the Language Environment program model, and consists of at least one enclave. Each process has an address space that is logically separate from those of other processes. Except for communications with each other using certain Language Environment mechanisms, no resources are shared between processes; processes do not share storage, for example. A process can create other processes. However, all processes are independent of one another; they are not hierarchically related.

Language Environment generally does not allow language file sharing across enclaves, nor does it provide the ability to access collections of externally stored data. However, the PL/I standard SYSPRINT file can be shared across enclaves. The Language Environment message file also can be shared across enclaves since it is managed at the process level. The Language Environment message file contains messages from all routines running within a process, making it a useful central location for messages generated during run-time.
Processes can create new processes and communicate to each other using Language Environment-defined communication, for such things as indicating when a created process has been terminated.

**Enclaves**

*Enclave* is the key feature of the program management model, a collection of the routines that make up an application. The enclave is the equivalent of any of the following:

- A run unit in COBOL
- A program, consisting of a main function and its sub-functions, in C
- A main procedure and all of its subroutines in PL/I
- A program and its subroutines in FORTRAN

The enclave consists of one main routine and zero or more subroutines. The main routine is the first to execute in an enclave; all subsequent routines are named as subroutines.

**Threads**

Each enclave consists of at least one *thread*, the basic instance of a particular routine. A thread is created during enclave initialization, with its own run-time stack that keeps track of the thread’s execution, as well as a unique instruction counter, registers, and condition-handling mechanisms. Each thread represents an independent instance of a routine running under an enclave’s resources.

Threads share all of the resources of an enclave. A thread can address all storage within an enclave. All threads are equal and independent of one another and are not related hierarchically. A thread can create a new enclave. Because threads operate with unique run-time stacks, they can run concurrently within an enclave and allocate and free their own storage. Because they may execute concurrently, threads can be used to implement parallel processing applications and event-driven applications.
6.14 LE program management full model

Figure 6-14 Program management full model

Program management full model

Figure 6-14 illustrates the full Language Environment program model, with its multiple processes, enclaves, and threads.

It shows each process is within its own address space. An enclave consists of one main routine, with any number of subroutines. A main routine might not be active at all times in a POSIX application if the thread in which the main routine executes terminates before the other threads that it created.

External data is available only within the enclave where it resides; notice that even though the external data may have identical names in different enclaves, the external data is unique to the enclave. The scope of external data, as described earlier, is the enclave. The threads can create enclaves, which can create more threads, and so on.
6.15 LE condition handling model description and terminology

- **Condition**
  - An exception that has been recognized by LE and thus is eligible to activate user and language condition handlers

- **Condition handler**
  - A routine invoked by LE that responds to conditions in an application.

- **Condition token**
  - Information about condition

- **Feedback code**
  - A 12 byte code returned from calls to LE routines

- **Resume cursor**
  - Contains the address where execution resumes after a condition is handled.

- **Stack frame**
  - The physical representation of the activation of a routine

---

**Condition handling model**

For single- and mixed-language applications, the Language Environment run-time library provides a consistent and predictable condition-handling facility. It does not replace current HLL condition handling, but instead allows each language to respond to its own unique environment as well as to a mixed-language environment.

Language Environment condition management gives you the flexibility to respond directly to conditions by providing callable services to signal conditions and to interrogate information about those conditions. It also provides functions for error diagnosis, reporting, and recovery.

Language Environment condition handling is based on the stack frame, an area of storage that is allocated when a routine runs and that represents the history of execution of that routine. It can contain automatic variables, information on program linkage and condition handling, and other information. Using the stack frame as the model for condition handling allows conditions to be handled in the stack frame in which they occur. This allows you to tailor condition handling according to a specific routine, rather than handle every possible condition that could occur within one global condition handler.

A unique feature of Language Environment condition handling is the condition token. The token is a 12-byte (AMODE 24/31) or 16-byte (AMODE 64) data type that contains an accumulation of information about each condition. The information can be returned to the user as a feedback code when calling Language Environment callable services. It can also be used as a communication vehicle within the run-time environment.
Condition handling terminology

The following terminology is used in application programs:

**Condition**
Any change to the normal programmed flow of a program. In Language Environment, a condition can be generated by an event that has historically been called an exception, interruption, or condition.

**Condition handler**
A routine invoked by Language Environment that responds to conditions in an application. Condition handlers are registered through the CEEHDLR callable service, or provided by the language libraries, by such constructs as PL/I ON statements.

**Condition token**
In Language Environment, a data type consisting of 12 bytes with structured fields that indicate various aspects of a condition, including severity, associated message number, and information that is specific to a given instance of the condition.

**Feedback code**
A condition token value used to communicate information when using the Language Environment callable services.

**Resume cursor**
Contains the address where execution resumes after a condition is handled. Initially, it will be the point in the application where a condition occurred when it is first reported to Language Environment.

**Stack frame**
The physical representation of the activation of a routine. The stack frame is allocated on a last in, first out (LIFO) basis and can contain automatic variables, information on program linkage and condition handling, and other information.

A stack frame is conceptually equivalent to a dynamic save area (DSA) in PL/I, or a save area in assembler.
6.16 LE condition handling steps

Condition handling steps
Language Environment condition handling is performed in three distinct steps: the enablement, condition, and termination steps.

Enablement step - Refers to the determination that an exception should be processed as a condition. The enablement step begins at the time an exception occurs in your application. In general, you are not involved with the enablement step; Language Environment determines which exceptions should be enabled (treated as conditions) and which should be ignored, based on the languages currently active on the stack. If you do not specify explicitly or as a default any services or constructs, the default enablement of your HLL applies.

Condition step - Begins after the enablement step has completed and Language Environment determines that an exception in your application should be handled as a condition. In the simplest form of this step, Language Environment traverses the stack beginning with the stack frame for the routine in which the condition occurred and progresses towards earlier stack frames.

Termination step - You can use the TERMTHDACT run-time option to set the type of information you receive after your application terminates in response to a severity 2, 3, or 4 condition. For example, you can specify that a message or dump is to be generated if the application terminates.
6.17 LE condition handling: Condition token

How conditions are represented

<table>
<thead>
<tr>
<th></th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>7</th>
<th>8</th>
<th>11</th>
</tr>
</thead>
<tbody>
<tr>
<td>severity code</td>
<td>message number</td>
<td>flags</td>
<td>facility id</td>
<td>instance specific information</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Severity code**
- 0000 - informational (I)
- 0001 - warning (W)
- 0002 - error (E)
- 0003 - severe (S)
- 0004 - critical (C)

**Message number**
- nnnn - hex message number

**Facility ID**
- CEE - Common run time
- EDC - C/C++ run time
- FOR - Fortran run time
- IBM - PL/I run time
- IGZ - Cobol run time

Figure 6-17 Condition token

**Condition token**

A condition token is used to communicate information about a condition to Language Environment, message services, callable services, and routines. The token is a 12-byte data type with fields that indicate the following information about a condition:

- **Severity of a condition.**
- **Associated message number:** identifies the message associated with the condition. The combination of Facility_ID and Msg_No uniquely identifies a condition.
- **Facility ID** identifies the owner of the condition (Language Environment, Language Environment component, or user-specified). It is also used to identify a file containing message text that is unique for the condition.
- **Instance-Specific Information (ISI)** is a field that is created if the condition requires that data or text be inserted into a message, for example, a variable name. This field also contains qualifying data, which can be used to specify data (input or output) to be used when a routine resumes processing after a condition occurs.

**Note:** Under Language Environment AMODE 64, the condition token is 16-bytes long and the Instance-Specific Information is an 8-byte field.
6.18 LE condition handling stack frame

Stack frame
A stack frame is an area of storage that can contain automatic variables, information on program linkage and condition handling, and other information. It is created through any of the following:

- A function call in C or C++
- Entry into a compile unit in COBOL
- Entry into a procedure or begin block in PL/I
- Entry into an ON-unit in PL/I

Each routine adds a unique stack frame, in a LIFO manner, to the Language Environment storage. User-written condition handlers (registered through CEEHDLR) are associated with each stack frame. In addition, HLL handling semantics can affect the processing conditions at each stack frame. For an illustration of the Language Environment run-time stack and its divisions into stack frames, see Figure 6-18.

Each Language Environment user condition handler is explicitly registered through the callable service CEEHDLR or through the USRHDLR run-time option. Language-defined handling mechanisms are registered through language-provided constructs, such as the PL/I ON statement or the C signal() function. When a routine returns to its caller, its stack frame is removed from the stack and the associated handlers are automatically unregistered.

Semantics associated with a routine are honored; for example, PL/I semantics on a return specify that any ON-units within a routine will be unregistered. If the USRHDLR run-time option is used, the user-written condition handler is registered at stack frame 0.
6.19 LE condition handling signaling

- Conditions can be signaled by:
  - A hardware-detected interrupt
  - An operating system-detected exception
  - A LE callable services
  - A user routine

Figure 6-19  Condition handling signaling

Signaling
A condition is signaled within Language Environment as a result of one of the following occurrences:
- A hardware-detected interrupt
- An operating system-detected exception
- A condition generated by Language Environment callable services
- A condition explicitly signaled within a routine

The first three types of conditions are managed by Language Environment and signaled if appropriate. The last may be signaled by user-written code through a call to the service CEESGL or signaled by HLL semantics such as SIGNAL in PL/I or raise in C.

When a condition is signaled, whether by a user routine, by Language Environment in response to an operating system or hardware-detected condition, or by a callable service, Language Environment directs the appropriate condition handlers in the stack frame to handle the condition.

Condition handling proceeds first with user-written condition handlers in the queue, if present, then with any HLL-specific condition handlers, such as a PL/I ON-unit or a C signal handler, that may be established. The process continues for each frame in the stack, from the most recently allocated to the least recently allocated. If a condition remains not handled after the stack is traversed, the condition is handled by either Language Environment or by the default semantics of the language where the condition occurred.
6.20 LE condition handling responses

- Conditions can be responded in these ways:

  > Resume

  > Percolate

  > Promote

**Figure 6-20 Condition handling responses**

**Responses**

Conditions are responded to in one of the following ways:

- **Resume** terminates condition handling and transfers control, usually to the location immediately following the point where the condition occurred.

  A resume cursor points to the place where a routine should resume; it can be moved by the callable service CEEMRCR to point to another resume point.

- **Percolate** defers condition handling for an unchanged condition because a condition handler declined to handle it. Condition handling continues at the next condition handler.

- **Promote** is similar to percolate in that it passes the condition on to the next condition handler; however, it transforms a condition to another condition, one with a new meaning. Condition handling then continues, this time with a new type of condition.

**Note:** Promote is not supported in AMODE 64.
## 6.21 LE storage management model

### Storage management terminology

- **Stack**
  
  An area of storage in which stack frames can be allocated.

- **Heap**
  
  An area of storage used by Language Environment routines. The heap consists of the initial heap segment and zero or more increments.

- **Heap element**
  
  A contiguous area of storage allocated by a call to the CEEGTST service. Heap elements are always allocated within a single heap segment.

- **Heap increment**
  
  Additional heap segments allocated when the initial heap segment does not have enough free storage to satisfy a request for heap storage.

- **Heap pool**
  
  A storage pool that, when used by the storage manager, can be used to improve the performance of heap storage allocation. This can improve the performance of a multi-threaded application.

---

**Figure 6-21 LE storage management terminology**

**Storage management model**

Common storage management services are provided for all LE-conforming programming languages; Language Environment controls stack and heap storage used at run-time. It allows single- and mixed-language applications to access a central set of storage management facilities, and offers a multiple heap storage model to languages that do not now provide one. The common storage model removes the need for each language to maintain a unique storage manager and avoids the incompatibilities between different storage mechanisms.
Heap segment  A contiguous area of storage obtained directly from the operating system.

Stack storage
Stack storage is the storage provided by Language Environment that is needed for routine linkage and any automatic storage. It is a contiguous area of storage obtained directly from the operating system. Stack storage is automatically provided at thread initialization.

A storage stack is a data structure that supports procedure or block invocation (call and return). It is used to provide both the storage required for the application initialization and any automatic storage used by the called routine. Each thread has a separate and distinct stack.

The storage stack is divided into smaller segments called stack frames, also known as dynamic storage areas (DSAs). A stack frame, or DSA, is dynamically acquired storage composed of a register save area and an area available for dynamic storage allocation for items such as program variables. Stack frames are added to the user stack when a routine is entered, and removed upon exit in a last in, first out (LIFO) manner. Stack frame storage is acquired during the execution of a program and is allocated every time a procedure, function, or block is entered, as, for example, when a call is made to a Language Environment callable service, and is freed when the procedure or block returns control.

For AMODE 64 support, users can specify a stack size above the bar, and can specify the maximum stack size.

Heap storage
Heap storage is used to allocate storage that has a lifetime not related to the execution of the current routine; it remains allocated until you explicitly free it or until the enclave terminates. Heap storage is typically controlled by the programmer through Language Environment run-time options and callable services.

For z/OS Language Environment, heap storage is made up of one or more heap segments comprised of an initial heap segment, and, as needed, one or more heap increments, allocated as additional storage is required. The initial heap may or may not be preallocated prior to the start of the application code, depending on the type of heap.

Each heap segment is subdivided into individual heap elements. Heap elements are obtained by a call to one of the heap allocation functions, and are allocated within the initial heap segment by the z/OS Language Environment storage management routines. When the initial heap segment becomes full, Language Environment gets another segment, or increment, from the operating system.

6.22 Debug Tool in the user environment

Language Environment supports the IBM Debug Tool

Use the Debug Tool as follows:

- Monitor and interrupt program flow
- Single step through an application
- Add, remove, enable, or disable breakpoints
- Display and change variables at breakpoints

Run-time options for debugging routines

Language-specific compiler options for debugging

IBM Debug Tool

Language Environment supports the IBM Debug Tool, a robust, interactive, interlanguage source-level debugging tool. Debug Tool helps you to examine, monitor, and control the execution of programs written in C/C++, COBOL, and PL/I. Debug Tool supports interactive and batch debugging of mixed-language applications.

Using the Debug Tool, you can:

- Monitor and interrupt the flow of a program to identify errors easily and correct them quickly
- Single step through your application or dynamically invoke Debug Tool when an error condition occurs
- Add, remove, enable, or disable breakpoints dynamically
- Display and change variables at breakpoints or monitor program variable changes as the program runs

Besides the language-specific compiler options important to debugging routines in Language Environment, there are also several language environment run-time options that affect debugging. When debugging AMODE 64 applications, the developer must be concerned about specific LE run time and language-specific compiler options to debug this kind of applications. The use of some compiler options (such as TEST or DEBUG) can affect the performance of your routine. See z/OS Language Environment Debugging Guide, GA22-7560, for a description of run-time options.

Figure 6-24 LE run-time options customization

LE run-time options customization

Figure 6-24 lists the sample jobs that are members of Language Environment sample library SCEESAMP. These sample jobs require other members of the SCEESAMP data set.

When you run the sample jobs, they create the CEEDOPT CSECT, an options control block which establishes the defaults for the options. The jobs invoke CEEXOPT during the assembly of the CEEDOPT module. When you modify the CEEXOPT macro invocation to change installation-wide defaults, you must specify each run-time option as either OVR or NONOVR.

The options in CEEUOPT override the default options in CEEDOPT or CEECOPT, unless NONOVR was specified for the option when CEEDOPT or CEECOPT was created.

The following example shows the IBM-supplied version of the CEEDOPT CSECT contained within the CEEDOPT member, with the default suboption values for each of the options.

```
CEEDOPT  CSECT

6.25 LE user exits

- Assembler user exit
- High-level language (HLL) user exit
- Abnormal termination user exit
- Load notification user exit
- Storage tuning user exit

User exits
Language Environment provides support for the following user exits:

- Assembler user exit
  The assembler user exit can be used to perform functions for enclave initialization, normal and abnormal enclave termination, and process termination.

- High-level language (HLL) user exit
  The HLL user exit can be used to perform functions for enclave initialization.

- Abnormal termination user exit
  The abnormal termination user exit can be used to collect problem determination data when Language Environment is terminating an enclave due to a not handled condition.

- Load notification user exit
  The load notification user exit can be used to improve performance by preventing frequently used modules from being loaded and deleted with each use. The load notification user exit is only available when Library Routine Retention (LRR) is used.

- Storage tuning user exit
  The storage tuning user exit provides a programming interface that allows you to collect Language Environment storage tuning information and to set the Language Environment run-time option values for STACK, LIBSTACK, HEAP, ANYHEAP and BELOWHEAP. The storage tuning user exit is available for CICS, and for non-CICS environments when LRR is used.

How to get IBM Redbooks

You can search for, view, or download Redbooks, Redpapers, Hints and Tips, draft publications and Additional materials, as well as order hardcopy Redbooks or CD-ROMs, at this Web site:

ibm.com/redbooks
The ABCs of z/OS System Programming is an eleven volume collection that provides an introduction to the z/OS operating system and the hardware architecture. Whether you are a beginner or an experienced system programmer, the ABCs collection provides the information that you need to start your research into z/OS and related subjects. If you would like to become more familiar with z/OS in your current environment, or if you are evaluating platforms to consolidate your e-business applications, the ABCs collection will serve as a powerful technical tool.

This volume describes the basic system programming activities related to implementing and maintaining the z/OS installation, and provides details about the modules used to manage jobs and data. The topics covered are:

- Overview of the parmlib definitions and the IPL process. The parameters and system data sets necessary to IPL and run a z/OS operating system are described, along with the main daily tasks for maximizing performance of the z/OS system.
- Basic concepts related to subsystems, how to use the subsystem services provided by IBM subsystems, and planning considerations for setting up and writing your own subsystem.
- Job management in the z/OS system using the job entry subsystems JES2 and JES3. Detailed discussion of how JES2 and JES3 are used to receive jobs into the operating system, schedule them for processing by z/OS, and control their output processing.
- The link pack area (LPA), LNKLST, authorized libraries, and the role of VLF and LLA components.
- SMP/E
- Language Environment
