The number of different types of devices that can benefit from MQTT implementations is growing every day. This paper shows how to use MQTT directly from the Arduino platform.

**Introducing Arduino**

Arduino is an open source electronics platform that enables you to enhance the capabilities of sensors and actuators. Arduino is built on top of a micro-controller that has a number of digital and analogue pins. These pins allow the board to sense its environment and respond to it. After the wiring is done, the board can be programmed using the Arduino programming language.

The syntax of this programming language is similar to the C programming language. The similarity also extends to use of libraries in C programs. That is, a regularly used piece of code could be hived off as a library that other programmers could include in their subsequent programs.

**Original publication:** This paper was originally published as a chapter in the IBM® Redbooks® publication, *Building Smarter Planet Solutions with MQTT and IBM WebSphere MQ Telemetry*, SG24-8054. The publication is available at the following website:

http://www.redbooks.ibm.com/abstracts/sg248054.html

**Additional resource:** You can learn more about the Arduino programming language at:

Simple Arduino circuit

This scenario shows a simple example of using Arduino and is taken from the Arduino development IDE. It provides an illustration of the circuit (Figure 1) and includes the source code (Example 1). The board is an Arduino Uno. In the circuit shown in Figure 1, the LED has its cathode connected to GND and the anode to pin 13.

![Arduino Uno circuit](image.png)

**Figure 1  Illustration of the Arduino circuit**

In general, the Arduino code runs such that the `setup()` is run once and only once, whereas the `loop()` function runs all the time unless the reset button on the board is pressed. When reset is pressed, the code execution begins again with `setup()` followed by looping the `loop()` function. To run the code, it is first compiled in the IDE and then uploaded to the board. The upload causes a reset automatically, and the execution begins as described before.

In Example 1, the LED connected to pin 13 is first designated as an OUTPUT pin. Then, in the `loop()` function, the LED is turned on using the built-in `digitalWrite()` function, where HIGH turns the LED ON and LOW turns it OFF. A delay of 1000 milliseconds (or a second) is introduced between these functions to give an impression of a blinking LED.

**Example 1  Source code for the sample circuit**

```c
// Blink
// Turns on an LED on for one second, then off for one second, repeatedly.
// This example code is in the public domain.

void setup() {
  // initialize the digital pin as an output.
  // Pin 13 has an LED connected on most Arduino boards:
  pinMode(13, OUTPUT);
}

void loop() {
  digitalWrite(13, HIGH); // set the LED on
  delay(1000);
  digitalWrite(13, LOW); // turn the LED off
  delay(1000);
}
```

MQTT and Arduino Devices
delay(1000); // wait for a second
digitalWrite(13, LOW); // set the LED off
delay(1000); // wait for a second

MQTT support in Arduino

The MQTT support in Arduino is provided through a library that is an implementation of the MQTT protocol V3. You can download this library at:

http://knolleary.net/arduino-client-for-mqtt/

This library should be included in the Arduino code and then appropriate functions are called for CONNECT, PUBLISH, SUBSCRIBE, and so forth. In our simple example, the code for CONNECT is added in the setup() function because the connection is made only once. The SUBSCRIBE code is added in the setup() function, and the message that has arrived is handled separately in a callback() function. The PUBLISH code is added in the loop() function.

Arduino and MQTT with a publish scenario

The network support for the Arduino board is provided using a shield, such as the Arduino Ethernet shield, which is connected to a modem or a network port using a standard network cable. This shield sits on top of the Arduino Uno board or another board.

For more information about the Arduino Ethernet shield, see:

http://arduino.cc/en/Main/ArduinoEthernetShield

Description of the scenario

This scenario illustrates an Arduino-based device that publishes to a topic using the MQTT protocol. The device is a simple temperature sensor that measures the ambient temperature every two minutes and publishes to a topic on an MQTT server.

Figure 2 on page 4 illustrates the circuit for this scenario.
Example 2 lists the source code for this scenario.

Example 2  Source code for the publish scenario

```c
#include <SPI.h>
#include <PubSubClient.h>
#include <DallasTemperature.h>
#include <OneWire.h>
#include <Ethernet.h>
#include <util.h>
#include <ctype.h>

//OneWire - http://www.arduino.cc/playground/Learning/OneWire
Dallas Temperature Sensor -
https://code.google.com/p/dallas-temperature-control-library/source/checkout
MQTT - http://knolleary.net/arduino-client-for-mqtt/

#define CLIENTID "ArduinoSensor"
#define TOPICNAME "sensor/temperature"
#define POLLINTERVAL 120000
#define DS18S20Pin 2
//Some MAC - DEAD BEEF FEED !
byte mac [] = {0xDE, 0xAD, 0xBE, 0xEF, 0xFE, 0xED} ;
//Connect to test.mosquitto.org server
byte server [] = { 85, 119, 83, 194 };
//Our MQTT client
PubSubClient arduinoClient(server, 1883, callback);
//Board on time
```
unsigned long boardTime = 0;
// Sensed temperature
float sensedTemperature = 0.0;
// Temperature in character format for publishing
char charTemperature[20];
// Temperature chip i/o
OneWire oneWire(DS18S20Pin); // on digital pin 2
DallasTemperature sensors(&oneWire);
// Handle message from mosquitto and set LEDs
void callback(char topic, byte payload, unsigned int length){
    // Do nothing as we are publishing ONLY.
}

void setup(void) {
    Serial.begin(9600);
    // Start the sensor
    sensors.begin();
    // Connect to the MQTT server - test.mosquitto.org
    beginConnection();
}

// Initialise MQTT connection
void beginConnection() {
    Serial.begin(9600);
    Ethernet.begin(mac);
    int connRC = arduinoClient.connect(CLIENTID);
    if (!connRC) {
        Serial.println(connRC);
        Serial.println("Could not connect to MQTT Server");
        Serial.println("Please reset the arduino to try again");
        delay(100);
        exit(-1);
    }
    else {
        Serial.println("Connected to MQTT Server...");
    }
}

void loop(void) {
    boardTime = millis();
    if ((boardTime % POLLINTERVAL) == 0) {
        getTemp();
        dtostrf(sensedTemperature,5,2,charTemperature);
        arduinoClient.publish(TOPICNAME, charTemperature);
    }
}

void getTemp() {
    // Send the command to get temperatures
    sensors.requestTemperatures();
    delay(100);
    sensedTemperature = sensors.getTempCByIndex(0);
    delay(150);
}
The description of the source code is as follows:

1. Add the `PubSubClient.h`, `OneWire.h`, and `DallasTemperature.h` header files and ensure that the associated `.cpp` files are available to the IDE.

2. The server to be connected to is defined as a byte array where each number represents the octets of an IP address.

3. Define the function `callback()` that receives control when a message for the subscribed topic arrives.

4. Define the client `arduinoClient` using the server IP address in the form of byte array, port number and the `callback()` function as the arguments.

5. Define the name of the client and the topic to be subscribed as constants.

6. As part of `setup()`, initialize the pins and initiate the connection. To initiate the connection, define (randomly) the MAC address for the device as `0xDEADBEEFFEED`. Change it to the MAC address as applicable to your installation.

7. As part of the `setup()` function, initialize the temperature sensor.

8. In the `loop()` function, obtain the temperature every 2.0 minutes, and publish it to an MQTT topic.

Running the scenario

To run the scenario, follow these steps:

1. Start an instance of the WMQTT utility.
2. Enter the IP address and port for the MQTT broker.
3. Click **Connect**.
4. Enter a topic for the subscription as `sensor/temperature/`.
5. Turn on the board.
6. Click **Subscribe** on the WMQTT utility.

   Temperatures appear in the WMQTT utility.

Arduino and MQTT with a subscribe scenario

The network support for the Arduino board is provided using a shield, such as the Arduino Ethernet shield. This shield is connected to a modem or a network port using a standard network cable. This shield sits on top of the Arduino Uno board or another board.

For more information about the Arduino Ethernet shield, see:

http://arduino.cc/en/Main/ArduinoEthernetShield

Description of the scenario

This scenario shows a device that subscribes to a topic using the MQTT protocol. In this example, an application reads in the temperature that is published by the device described in “Arduino and MQTT with a publish scenario” on page 3. This application has logic in it to determine whether the temperature is within predetermined limits. If the temperature is within limits, the message YES,YES is published. If the temperature is not within limits, a message
NO, YES or YES, NO is published, depending on whether the lower limit or higher limit, respectively, was breached.

Figure 3 shows the circuit for this scenario.

![Figure 3](https://via.placeholder.com/150)

Figure 3  Subscribe scenario circuit

In this circuit, three LEDs have anodes connected to pins 7, 8, and 9, respectively. Their cathodes are grounded. The resistors are 220 Ω to avoid damaging the LED. These three resistors approximately replicate an RGB LED behavior. That is, at any point, only one of the LEDs will be glowing to indicate NORMAL, HIGH, or LOW situations.

Example 3 shows the source code for this scenario.

Example 3  Source code

```c
#include <Ethernet.h>
#include <EthernetUdp.h>
#include <EthernetServer.h>
#include <EthernetClient.h>
#include <util.h>
#include <Dns.h>
#include <Dhcp.h>
#include <SPI.h>
#include "PubSubClient.h"

//Pin definition
#define NORMALPIN 7
#define LOWPIN 8
#define HIGHPIN 9

//MQTT definition
#define CLIENTID "ArduinoActuator"
```
# define TOPICNAME "sensor/temperature/monitor"
/
By default Pin 7 will be ON to denote that the temperature is between HIGH and LOW
limits.
When the limits are breached, then Pin 7 goes OFF and either Pin 8 or Pin 9 goes
ON depending on which limit was breached.
Pin 7 Pin 8 Pin 9
NO,NO 0 1 1 Meaningless - this should not happen!
NO,YES 0 1 0 LOW limit breached
YES,NO 0 0 1 HIGH limit breached
YES,YES 1 0 0 NORMAL - No limits are breached.
/
// CHANGE MAC ADDRESS TO THAT APPEARS ON THE ETHERNET SHIELD
byte mac [] = {0xDE, 0xAD, 0xBE, 0xEF, 0xFE, 0xED} ;
/
//Connect to test.mosquitto.org server
byte server [] = { 85, 119, 83, 194 };
//Handle message from mosquitto and set LEDs
void callback(char topic, byte payload, unsigned int length) {
  int i=0; char buffer [length] ;
  for(i=0;i<length;i++) {
    buffer [i] = char((payload + i)) ;
  }
  String payLoadData = buffer ;
  setPins(payLoadData) ;
}
//Our MQTT client
PubSubClient arduinoClient(server, 1883, callback) ;
void setup() {
  //Set pins to indicate normal
  beginPins() ;
  //Connect to the MQTT server - test.mosquitto.org
  beginConnection() ;
}
//Initialise LED pins
void beginPins() {
  pinMode(NORMALPIN, OUTPUT) ;
  pinMode(LOWPIN, OUTPUT) ;
  pinMode(HIGHPIN, OUTPUT) ;
  digitalWrite(NORMALPIN, HIGH) ;
  digitalWrite(LOWPIN, LOW) ;
  digitalWrite(HIGHPIN, LOW) ;
}
//Initialise MQTT connection
void beginConnection() {
  //Serial.begin(9600);
  Ethernet.begin(mac) ;
  int connRC = arduinoClient.connect(CLIENTID) ;
  if (connRC) {
    arduinoClient.subscribe(TOPICNAME) ;
  } else {
    Serial.println(connRC) ;
  }
}

void loop() {
arduinoClient.loop();
}
void setPins(String s) {
    // BEGIN
    // The code between BEGIN and END turns ON all the LED for a second before turning ON
    // or OFF the LED
to denote the temperature range. If the temperature source does not fluctuate too
    // piece of code can give an impression that the Arduino is "working".
    // END
    digitalWrite(NORMALPIN, HIGH);
digitalWrite(LOWPIN, HIGH);
digitalWrite(HIGHPIN, HIGH);
delay(1000);
s.trim();
int temperatureLimits[] = {1,1};
if (s.substring(0,s.indexOf(',')) == "YES") { temperatureLimits [0] = 1; }
if (s.substring(0,s.indexOf(',')) == "NO") { temperatureLimits [0] = 0; }
if (s.substring(s.indexOf(',')+1) == "YES") { temperatureLimits [1] = 1; }
if (s.substring(s.indexOf(',')+1) == "NO") { temperatureLimits [1] = 0; }
int ledPins [] = {NORMALPIN, LOWPIN, HIGHPIN};
int ledStatus [] = {1, 0, 0}; //Default is NORMAL, so NORMAL pin is ON
for (int i=0; i<2; i++) {
    if (temperatureLimits [i] == 0) { ledStatus [0] = 0; ledStatus [i+1] = 1; }
}
for (int j=0; j<3; j++) {
digitalWrite(ledPins[j],ledStatus[j] );
}
}

The description of the source code is as follows:
1. Add the PubSubClient.h header file, and ensure that this header file and the associated
   .cpp files are available to the IDE.
2. Define the server to be connected to as a byte array, where each number represents the
   octets of an IP address.
3. Define the function callback() that receives control when a message for the subscribed
   topic arrives.
4. Define the arduinoClient client using the server IP address in the form of byte array, port
   number, and the callback() function as the arguments.
5. Define the name of the client and the topic to be subscribed as constants.
6. As part of the setup() function, initialize the pins and initiate the connection. To initiate the
   connection, define (randomly) the MAC address for the device as 0xDEADBEEFEED.
   Change it to the MAC address that is burnt onto the device.
7. After initiating the connection, subscribe to the topic name in which you are interested.
   The callback() function calls the setPins() function to turn ON or OFF the LEDs as
   described previously.
Running the scenario

To run the scenario, follow these steps:

1. Start an instance of the WMQTT utility.
2. Enter the IP address and port for MQTT broker.
3. Click **Connect**.
4. Enter a topic for publication as `sensor/temperature/monitor`.
5. Type in the message **YES,YES** and click **Publish**.
6. Watch the LEDs turn **ON** or **OFF**.

To run this scenario, set up an MQTT server and a client. Then, publish to the sensor/temperature/monitor topic the message **YES,YES, NO,YES**, or another setting.

The author who wrote this paper

This paper was produced by a specialist working at the International Technical Support Organization, Raleigh Center.

**Nagesh Subrahmanyam** is an IT Specialist in India. He has over 10 years of experience in the field spanning IBM z/OS®, WebSphere® MQ, WebSphere Message Broker and XML technologies. He holds a Bachelor’s degree in Mechanical Engineering from National Institute of Technology, Jamshedpur. His areas of expertise include Java and lately the Arduino platform. He has contributed a couple of articles on the IBM developerWorks® website, and co-authored IBM Redbooks publications about XML and z/OS. He has also submitted a WebSphere MQ SupportPac.

Now you can become a published author, too!

Here’s an opportunity to spotlight your skills, grow your career, and become a published author—all at the same time! Join an ITSO residency project and help write a book in your area of expertise, while honing your experience using leading-edge technologies. Your efforts will help to increase product acceptance and customer satisfaction, as you expand your network of technical contacts and relationships. Residencies run from two to six weeks in length, and you can participate either in person or as a remote resident working from your home base.

Find out more about the residency program, browse the residency index, and apply online at: [ibm.com/redbooks/residencies.html](http://ibm.com/redbooks/residencies.html)
